Agenda

- ▶ Check-in, introductions and logistics
- ▶ Advisory meeting goals and agenda review
- ▶ Project overview
- ▶ Science reports
- ▶ Final discussions / responses

- ▶ Appendices at back
 - ▶ Organization chart
 - ▶ Leadership staff and advisory committee names / emails
 - ▶ Products to date (posters and talks)
 - ▶ Original project goals and timelines

Advisory committee meeting agenda

Time start	Topic	Speaker/s - Organizer
8:45	Logistics/connections/self-introductions	Goddard (Strauss)
9:00	Overview of project and progress	Strauss (Goddard)
9:30	Phenomics I: Plat materials, <i>in vitro</i> and transgenic adaptation studies, GWAS phenotyping methods, greenhouse management	Ma (Peremyslova, Nagle, Jiang, Strauss)
10:15	Phenomics II: Experimental imaging and image analysis pipeline, DEV gene study example/s	Nagle (Ma, Peremyslova, Jiang)
11:00	BREAK	
11:15	Phenomics III: Machine vision analysis systems	Li (Yuan, Damanpreet, Nagle)
12:15	Lunch	
1:00	GWAS pipeline and results	Nagle (Jiang)
1:45	Advances in integrated analysis of GWAS and eQTN studies in <i>Populus trichocarpa</i>	Muchero – ORNL and UT
2:15	BREAK	
2:30	Broader impacts: Education and curricula, social science	Hall (Well, Emery)
3:30	Summing up: Review of action items and suggestions	Strauss (Goddard)

Basic science ideas behind work - 1

- ▶ The capacity for regeneration of transgenic plants (aka “transformation” or “RT”) remains a major obstacle to broad, low cost use of transgenic methods for research and biotechnology
- ▶ Little is know about why species and genotypes vary so widely in their amenability to transformation
- ▶ The ability to accurately phenotype plants during RT is a major barrier to understanding and analysis, and a limiting factor for GWAS statistical efficiency
 - ▶ Developments in imaging and image analysis may be game changers

Basic science ideas behind work - 2

- ▶ Poplars are good model systems due to their extensive in vitro biology, and genomic resources
 - ▶ Reference genome, resequenced association population, low LD among wild trees
- ▶ GWAS may enable genes that control various part of the RT process to be identified, and thus the relevant physiological processes inferred, further studied, and the genes possibly employed as reagents to improve RT
- ▶ Cognitive approaches to education and outreach may empower teachers and students to better understand—and thus make better decisions as citizens, activists, and professionals—about complex GMO issues

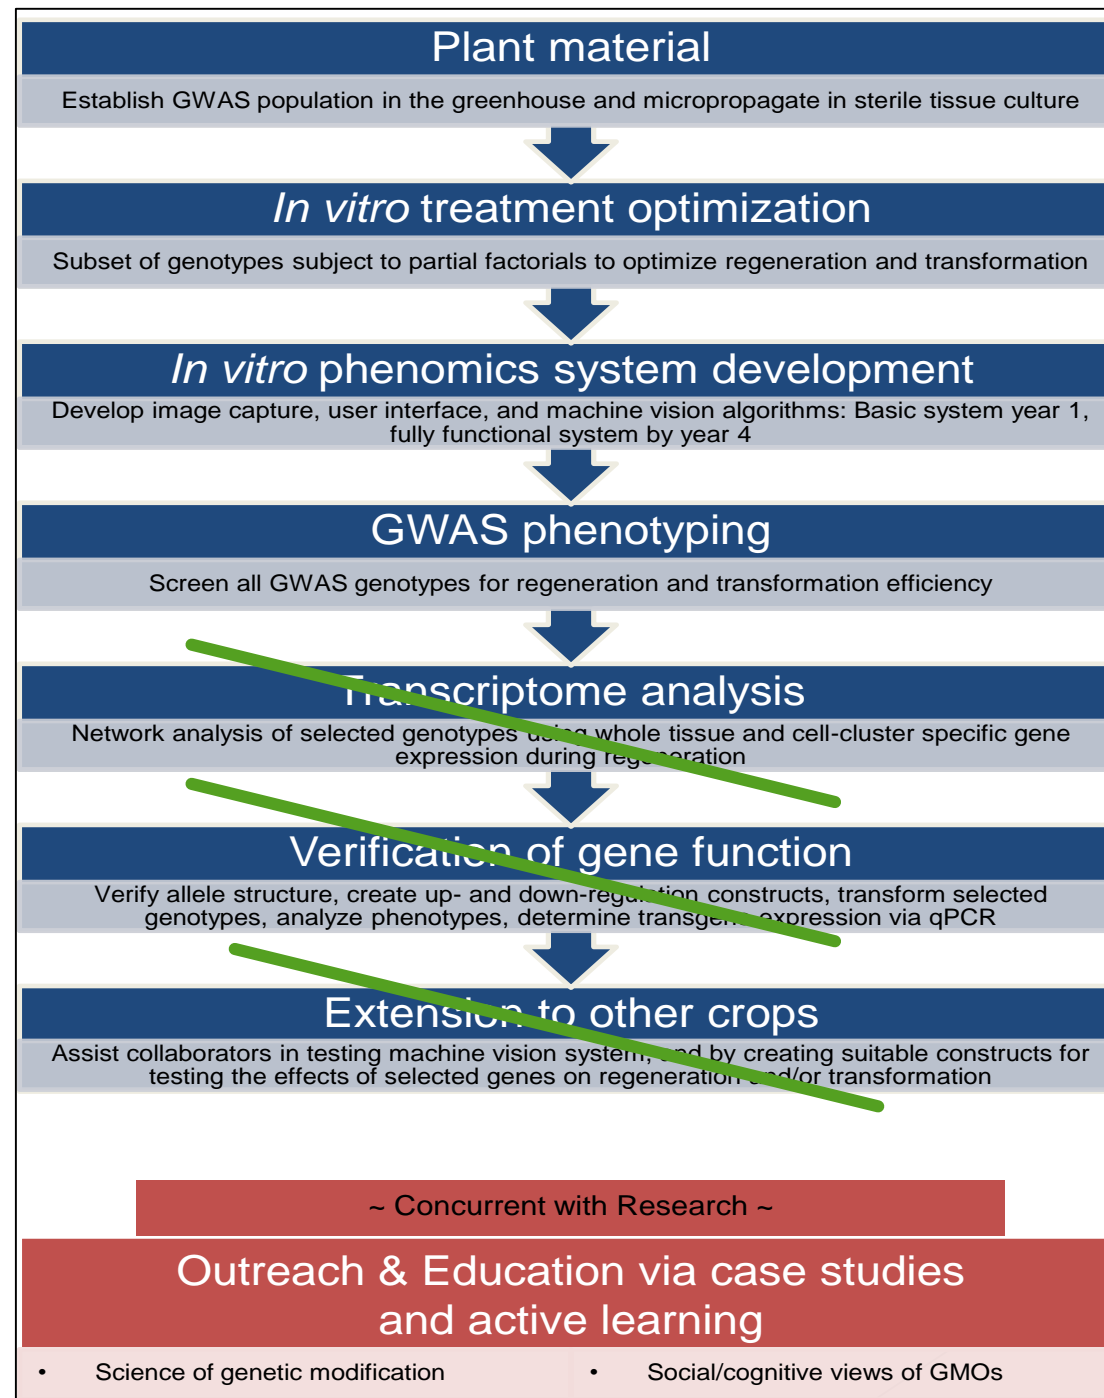

Project objectives in brief

- ▶ Explore a variety of RT methods to maximize variation (and thus GWAS “mapability”) in RT responses
- ▶ Develop new phenomic tools, including an image capture and generalizable machine-vision system, to precisely determine in vitro phenotypes
- ▶ Using GWAS, map sets of alleles that are associated with variation in RT frequency
- ▶ Study cognitive processes with respect to GE crops, develop case studies and new teaching materials, and deliver them to rural and underserved communities in the Pacific Northwest

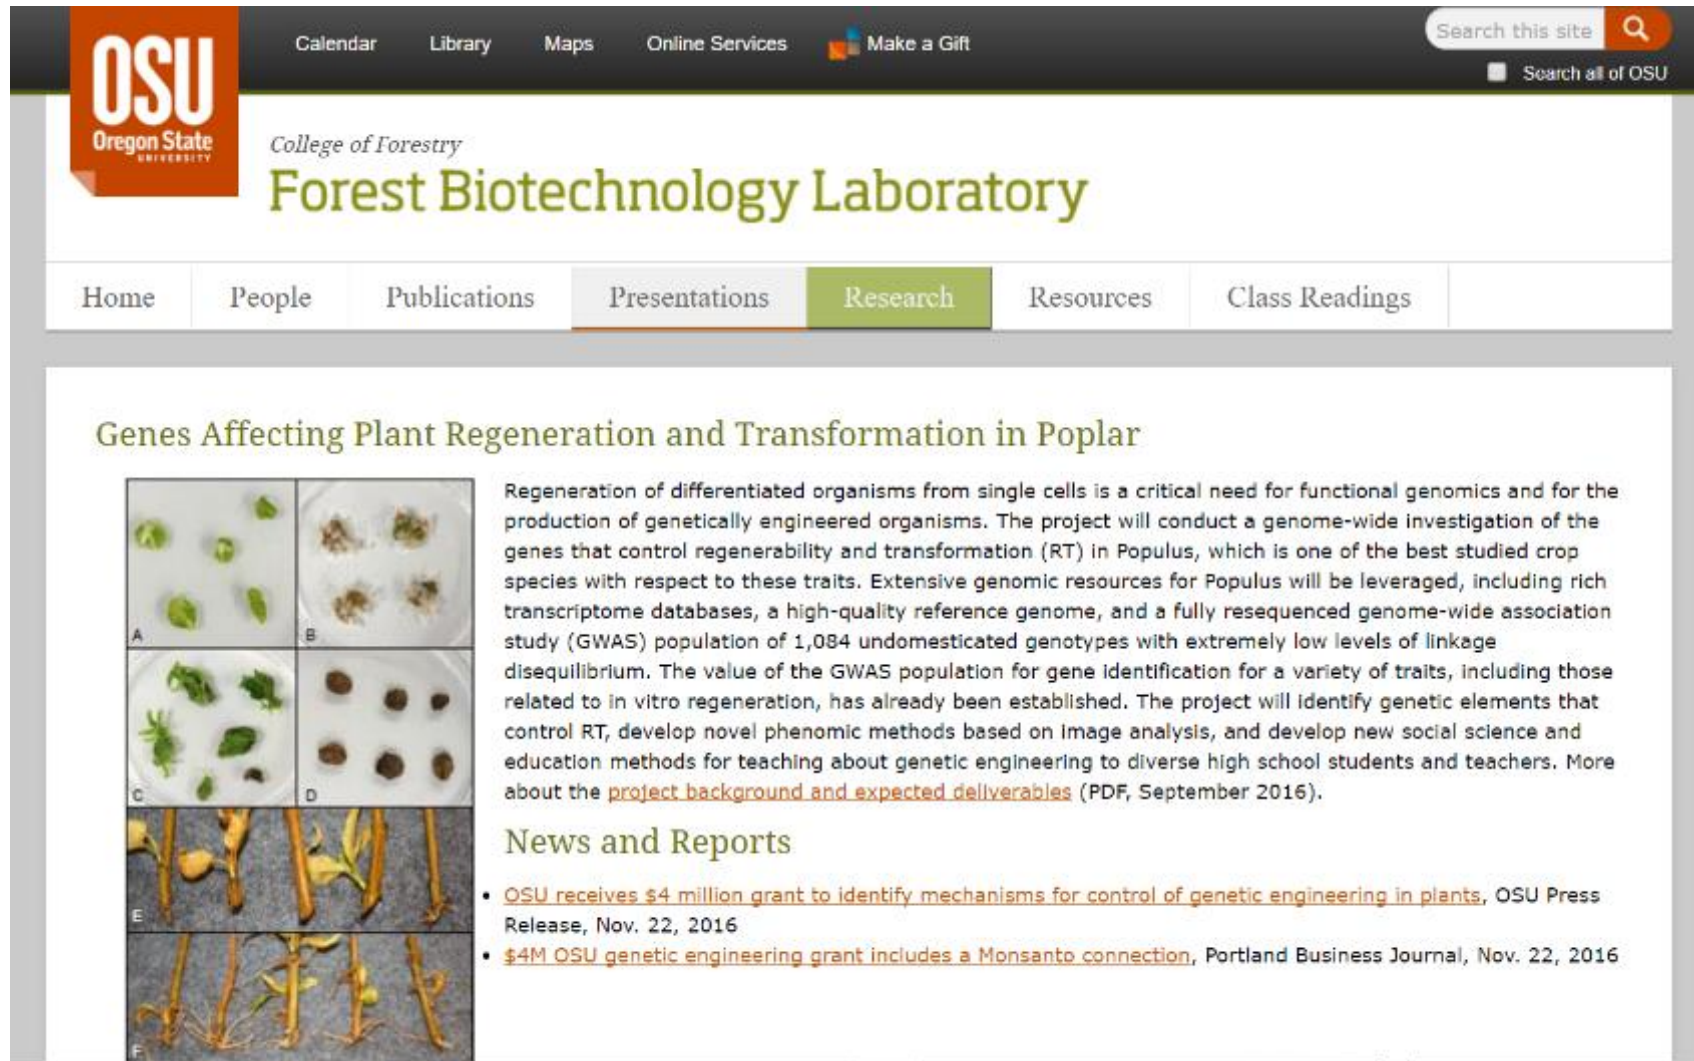

Sequence of activities

Communications and data

- ▶ **Weekly meetings** - 1+ hour each (to be extended to two shortly)
- ▶ **Monthly meetings** - More general overviews of plans and new initiatives
- ▶ **Shared cloud server** for exchanging files and analysis results (Box). Development of project database in this or other platforms.
 - ▶ Other sharing and communication platforms considered but not adopted to date
- ▶ Simple project web site, plus normal pub/poster web sites
 - ▶ Plus twitter announcements
- ▶ Core data stored in 2-3 places on cloud and hard drive (Box, Google, external drives)

Genes Affecting Plant Regeneration and Transformation in Poplar

Regeneration of differentiated organisms from single cells is a critical need for functional genomics and for the production of genetically engineered organisms. The project will conduct a genome-wide investigation of the genes that control regenerability and transformation (RT) in *Populus*, which is one of the best studied crop species with respect to these traits. Extensive genomic resources for *Populus* will be leveraged, including rich transcriptome databases, a high-quality reference genome, and a fully resequenced genome-wide association study (GWAS) population of 1,084 undomesticated genotypes with extremely low levels of linkage disequilibrium. The value of the GWAS population for gene identification for a variety of traits, including those related to *in vitro* regeneration, has already been established. The project will identify genetic elements that control RT, develop novel phenomic methods based on image analysis, and develop new social science and education methods for teaching about genetic engineering to diverse high school students and teachers. More about the [project background and expected deliverables](#) (PDF, September 2016).

Summary of project budget - 1

PI/coPIs/Key - 0.6 to 3 months per year

- ▶ Strauss - 5 years (PI)
- ▶ Jiang - 5 years (statistics)
- ▶ Li - 3 years (machine vision)
- ▶ Hall - 2 years (social science)
- ▶ Well - 3 years (education/outreach)
- ▶ Muchero - 2 years (GWAS)

- ▶ Postdoc (gene constructs and bioinformatics)
 - ▶ 1 year full-time, final year

Summary of project budget - People

- ▶ Technicians - all years
 - ▶ 2-3 months/year - Project manager, Amanda Goddard
 - ▶ 4-6 months/year - Cathleen Ma (25 years experience)
 - ▶ Full-time - FRA, Kate Peremyslova
 - ▶ 6 months/year - Temp, Julie Kucinski
- ▶ Graduate Research Assistant - Time remaining
 - ▶ Machine vision (16/36 months)
 - ▶ In vitro/GWAS (29/36 months)
 - ▶ Social science/education (21/36 months)
- ▶ Student aides (undergraduate)
 - ▶ 3-18 months per year

Summary of project budget - major items - 1

- ▶ Growth chambers - 164 K ✓
- ▶ Custom imaging system - 90 K ✓
- ▶ Custom Petri dish transfer trays/system - 5-10 K ✓
- ▶ Mediaclave and Mediajet (large batch media prep/pour) - 42 K ✓
- ▶ Centrifuge and ultra freezer - 18 K ✓
- ▶ Laminar flow hood - 5 K ✓
- ▶ **~300 K inception to date**

Summary of project budget (Inception to date / original budget shown)

- ▶ Services/supplies, 5 years - 111 K / 262 K
- ▶ Participant support costs, 3 years - SMILE - 18K / 112 K
- ▶ Grad student tuition, 5 years - 72.5 K / 184 K
- ▶ Personnel, 5 years - 671 K / 2.0 M
- ▶ Indirects, 5 years - 486 K / 1.1 M
- ▶ **Total cost, 5 years - 1.9 M / 4.0 M**

Major changes from submitted proposal - 1

Realizations about scale and biological complexity of work

- ▶ Use of maximal samples of genotypes
 - ▶ Statistical information on weakness of GWAS re. potential for false discovery
 - ▶ Availability of additional resequenced wild cottonwood genotypes (from ~1,000 to 1,300; ~300 with SNP data yet to be provided)
- ▶ *In vivo* source materials for GWAS: Cannot afford to maintain many hundreds of genotypes *in vitro*, thus must use sterilized greenhouse materials and contamination a serious problem
- ▶ Logistical issues of sizes of experiments (take many months, management, vigor, uniformity, sterilization of materials)
- ▶ Need to better and systematically explore *in vitro* and transformation conditions for efficient GWAS (expanded *in vitro* optimization from 1 year to 2 years)
- ▶ In short: Manpower is limiting given cuts, new realities

Major changes from submitted proposal - 2

Realizations about scale and biological complexity of work

- ▶ Complexity, effort needed to develop visualization and machine vision tools into routine, portable, efficient, and web-based systems for biologists was underestimated
 - ▶ Gap between interests/skills, and manpower, of machine learning staff and biologists
- ▶ Computation requirements for machine vision and advanced GWAS, especially with resampling, large SNP datasets, high resolution or hyperspectral images
 - ▶ Means for linkages to CyVerse, computing grids, Kbase or others
- ▶ Challenges to choosing and interpreting GWAS algorithms from many available, but often with substantial limitations re. sample size, speed, ability to handle complex models and non-normal data, and more
- ▶ Challenges to choosing GWAS tools, and interpreting GWAS results re. candidate genes and regulatory motifs, given predominance of non-coding SNPs, locations outside of genes, complexity of real gene regulation
- ▶ Long delays in obtaining key reagents such as Agro strains and DEV genes for tests (legal hoops and bottlenecks), and needing to often subclone/modify what we are provided
- ▶ In short, manpower and computation limitations serious

Planned publications

▶ Regeneration / transformation treatment optimization

- ▶ Regeneration
- ▶ Genetic variation / heritability
- ▶ Transformation

▶ Phenomics

- ▶ Imaging system pipeline, comparison to human scoring
- ▶ Machine vision annotation system
- ▶ Machine vision prediction algorithms and efficiency

▶ GWAS

▶ In vivo

- ▶ Shoot regeneration
- ▶ Root regeneration

▶ In vitro

- ▶ Direct regeneration
- ▶ Indirect regeneration
- ▶ Transformation treatments (Agro strains (2), acetysyringone (2), DEV gene (2))

Agenda

Phenomics I: Plant materials, *in vitro*
and transgenic adaptation studies,
GWAS phenotyping methods,
greenhouse management

October 3, 2019

Cathleen Ma, Kate Peremyslova, and
Julie Kucinski

Outline

- Field collection and materials storage
- Plant care and greenhouse management
- *In vivo* stem regeneration study
- *In vivo* rooting study
- *In vitro* regeneration optimization
- *In vitro* transformation optimization
- *In vitro* GWAS regeneration

Field collection and material storage

- Aim is to collect dormant cuttings for GWAS study
- Collection and storing
 - Harvest four 6” cuttings from new growth branches from each genotype
 - Placed cuttings separately in two Ziplock bags/genotype (2 cuttings/bag) with water proof labels
 - Stored in RH and FRL freezers
 - Materials are used for *in vivo* and *in vitro* studies

Date collected	# genotypes collected from lower Marchel	# genotypes collected from clone bank	Total # of genotypes collected from both field sites	Materials storage condition	# genotypes for <i>in vivo</i> stem regeneration and rooting study	# phases
Feb. 2017	833	0	833	4°C	~600	Phase 1-3
Jan. 2018	314	662	976	-10°C	~600	Phase 4-7
Feb. 2019	204	295	499	-10°C	~20	Phase 8

Plants are growing at Lower Marchel and clone bank

Collection at Lower Marchel in 2017

Collection in clone bank in 2018

Collected dormant cuttings

Plant care and greenhouse management

- Aim is to grow healthy and uniform plants for GWAS
- Dormant cuttings were used for *in vivo* stem regeneration and rooting studies, then rooted plants were transplanted in 4x9.5” long tube pots and grew in greenhouse for GWAS study
- ~1,000 genotypes (2 plants/genotype) were grown in two locations

Plant care and greenhouse management – 2 greenhouses

- One set of plants used for the study are randomly growing closed greenhouse supplemented with light 16h at 24°C
 - Plants are used year around by trimming and fertilizing with slow releaser every 3 months
 - Disease and pest monitoring carried out weekly and spray control in timely manner by OSU greenhouse crew
- Another set of plants are randomly growing in open greenhouse with natural light and go dormant in winter
 - The plants also are trimmed and fertilized every 3 months in growing season
 - These plants are used for backup

Plants grown in two greenhouses

Closed greenhouse

Open greenhouse

In vivo GWAS study: stem and root regeneration (completed)

- Goal is to discover genes associated with regeneration *in vivo* conditions
- Shoots first covered then roots, though mostly done at same time
- To select optimum hormone TDZ concentration, we first tested 4 levels of TDZ (0, 0.1, 0.5, and 1mg/L) in 10 genotypes for shoot development
 - Dormant cuttings were cut with one bud and planted in 50ml Flacon tube with water in head greenhouse
 - Eppendorf tube with 100 ul different levels of TDZ placed on freshly cut stem tip to hold treatment and maintained moisture for 2 days
 - Repeat application with same amount and levels TDZ for 2 days weekly to promote shoot regeneration
 - Data and imaging collected each week for five weeks
 - Manual score callus and shoot formation at week 3 and 5

TDZ was tested to aid in callus and shoot formation from stems

0.0 mg/L TDZ

0.5 mg/L TDZ

TDZ (0.5 mg/L) promoted shoots and genetic variation

TDZ (0.5 mg/L) continued: Genetic variation in stem regeneration

Callus formation scoring system for stem regeneration study

0

1

2

3

0= no callus

1= small callus

2= medium callus

3= large callus

Shoot formation scoring system

0= no shoot

1= 1-2 shoots

2= 3-5 shoots

3= more than 5 shoots

1,278 genotypes studied for *in vivo* stem regeneration over 8 experiments

GWAS Phase	# Genotypes studied	Date of cuttings collected	Starting dates	Dates in soil
1	200	2/8-10/17	8/3/2017	9/6/2017
2	210	2/8-10/17	8/29/2017	10/4/2017
3	200	2/8-10/17	10/5/2017	11/20/2017
4	200	1/16-17/18	3/16/2018	5/4/2018
5	196	1/16-17/18	5/9/2018	6/22/2018
6	198	1/16-17/18	7/25/2018	9/7/2018
7	57 (119 repeat)	1/16-17/18	9/26/2018	11/7/2018
8	17 (183 repeat)	2/6-7/19	3/18/2019	4/22/19
Total	1,278 (1,580)			

In vivo GWAS study: Rooting (completed)

- Goal is to discover genes associated to rooting *in vivo* condition
- Methods and materials
 - Dormant cutting was cut with one bud and planted in 50ml Flacon tube water without any hormone application in head house
 - 200 genotypes each phase; Total 8 phases including repetition for some genotypes
 - Light is provided by fluorescent tubes with a 16-h photoperiod and temperature is 22-25°C
 - Tubes were filled with fresh tap water every 3-4 days
 - Data and imaging collected each week for five weeks

1,224 genotypes have been used for *in vivo* GWAS rooting

GWAS Phase	# Genotypes studied	Date of cuttings collected	Start dates	Dates in soil
1	195	1/16-17/18	11/13/2018	12/15/2018
2	190	1/16-17/18	12/17/2018	1/28/2019

4	200	1/16-17/18	3/21/2018	5/4/2018
5	193	1/16-17/18	5/11/2018	6/22/2018
6	198	1/16-17/18	7/27/2018	9/7/2018
7	57 (115)	1/16-17/18	9/28/2018	11/6/2018
8	17 (183)	2/6-7/19	3/19/2019	4/22/19
Total	1,224 (1,522)			

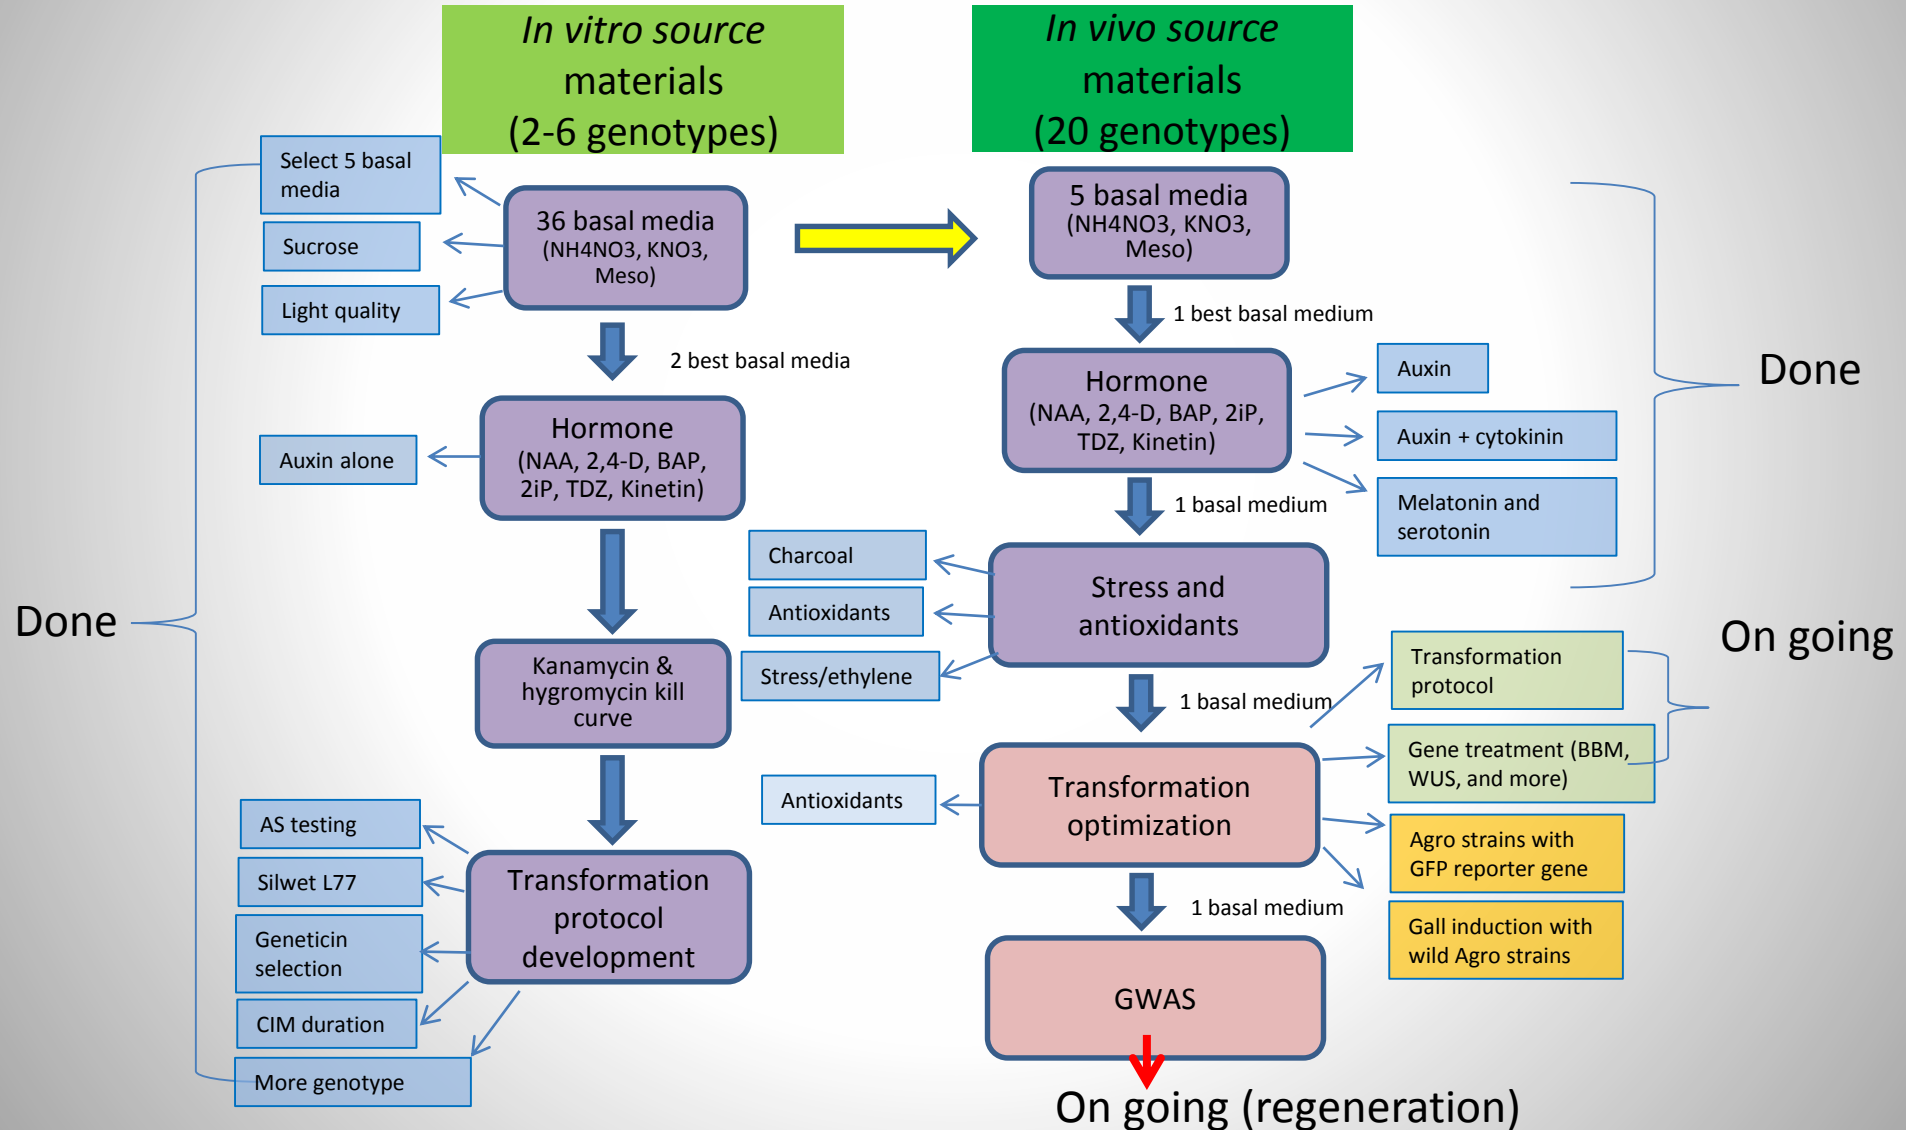

Adventitious stem roots

Adventitious basal roots

Goal is to determine optimal treatment and condition to be applied to GWAS to maximize genetic variance and minimize environmental variance

In vitro study equipment purchased

Percival Scientific Growth Chambers:
In order to reduce condensation we used
plastic boxes to hold unsealed Petri dishes

Integra mediajet and mediaclave

Twelve optimization experiments including 163 treatments have been completed

Experiment ID	Title of experiment	Goal of experiment	# of treatments	# genotypes tested
E1	Direct vs. indirect regeneration	Study the effect of two regeneration pathways on organogenesis	2	20
E2	36 basal media screen (in vitro)	Screen big range of macro and micro nutrients and study their effect on regeneration	36	2
E3	5 basal media test (in vitro)	Select the best basal medium that gives 50% of genotypes in regeneration	5	5
E3	5 basal media test (in vivo)	Select the best basal medium that gives 50% of genotypes in regeneration	5	20
E4	Varying [sucrose] (in vitro)	Test whether cottonwood grow better on low level of sucrose	8	4
E5	Various auxins (in vitro)	Test what types of auxin at which level is good for regeneration	18	6
E5	Various auxins (in vivo)	Test what types of auxin at which level is good for regeneration	9	20

In vitro experiments: Continued

Experiment ID	Title of experiment	Goal of experiment	# of treatments	# genotypes tested
E6	Various auxin, cytokinin combos (in vivo)	Study the effect of various auxin and cytokinin combination on organogenesis	36	18
E7	Melatonin, serotonin effects (in vivo)	Study the effect of newly discovered plant hormone melatonin and serotonin on organogenesis	8	19
E8	PPM (Plant Preservative Mixture) and benomyl effect (in vivo)	Test the efficacy of PPM and benomyl in controlling contamination	7	8
E9	LA (Lipoic Acid) effect (in vivo)	Study the effect of antioxidants LA on organogenesis	7	16
E10	AC (Activated Charcoal) and VC (Vitamine C) (Ascorbic Acid) effect (in vivo)	Study the effect of AC and antioxidant VC on organogenesis	7	16
E11	AgNO ₃ effect (in vivo)	Study the effect of ethylene inhibitor AgNO ₃ on organogenesis	7	16
E12	Light spectrum & intensity effect (in vivo)	Study the effect of different light spectrum and intensity on callus and shoot formation	8	4

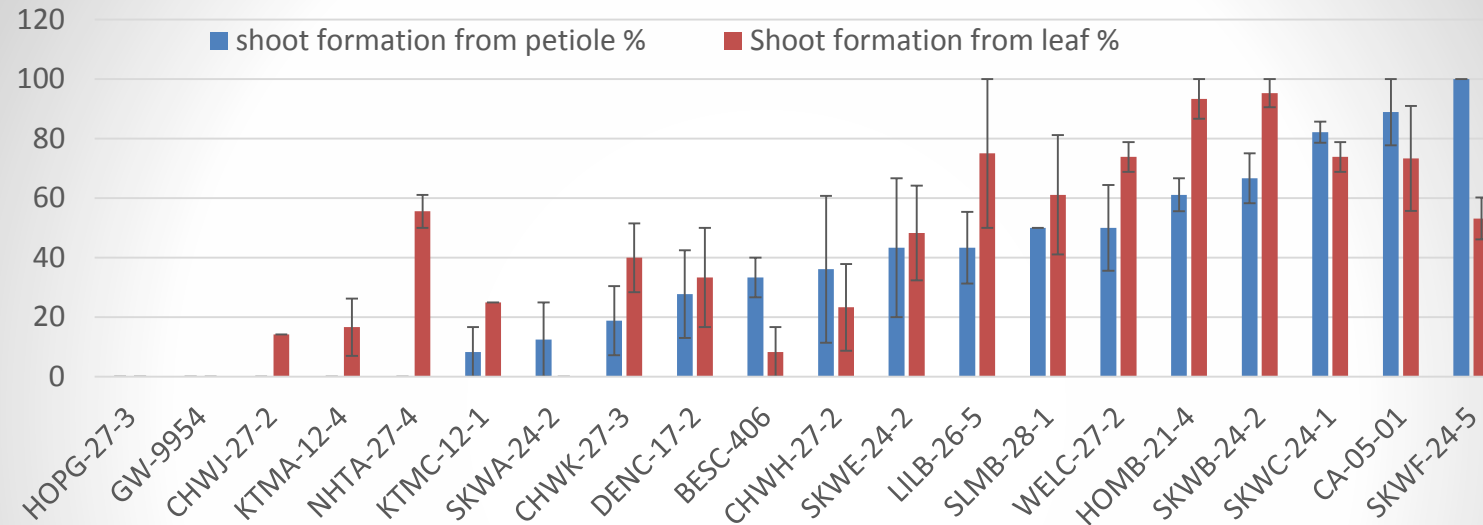

Data and image collection and some issue *in vitro* regeneration optimization

- Proportion of callus, shoot and root, average size of callus and mean number of shoots and roots
 - Longest shoots were assessed after 9 weeks (6 weeks on SIM)
- RGB images taken at 0 and 3 weeks on CIM and 2, 4, and 6 weeks on SIM
- We used 3 explant types (leaf, stem, and petiole) for the study
- We found the leaf and petiole often necrotic after sterilization
- Therefore we have only used stem explants for *in vitro* GWAS study

Indirect regeneration system gave 90% response among genotypes tested (CIM then SIM)

CA-05-01 petiole explant

LILB 26-5 petiole explant

55 % genotypes formed shoots through direct regeneration (direct to SIM)

SLMB 28-1 petiole explant

SLMB 28-1 leaf explant

We selected auxin and cytokinin types and concentrations for the testing based on literature in *Populus trichocarpa*

DB hormone combinations showed high genotype and low explant variance

DB1 hormones gave high H^2 and much genotype variance

Treatment	DB1	DB2	DB3	DB4	DB5	DB6
2.4-D (mg/L)	0.01	0.05	0.1	0.01	0.05	0.1
BAP (mg/L)	0.5	0.5	0.5	1	1	1

Transformation optimization

- Goal is to test various factors that influence transformation rate
- Methods and materials
 - *In vivo* stem explants (2-3mm)
 - Agrobacterium strain AGL1 containing 2X35S::eGFP or DS-Red
 - 1% Tween 5 min, 70% ethanol 5 min, 20% bleach 20 min (10 min in vacuum), and 4 washes
 - 2-20 genotypes, 20 explants/plate, 3-4 plates/treatment/genotype
- Data and images taken
 - RGB and hyperspectral imaging after 3 and 7 weeks
 - Manual score callus and shoot formation, GFP callus and shoot production at week 3 and 7

14 transformation optimization experiments including 54 treatments done or nearly so

Experiment ID	Title of experiment	Goal of experiment	# of treatments	# genotypes tested
T1	AS vs. no AS	Test whether acetosyringone (AS) enhances Agrobacterium-mediated transformation in cottonwood	2	20
T2	Antioxidants (Lipoic acid)	Test if lipoic acid can reduce explants browning and increase transformation rate	4	20
T3	Pre-culture vs. no pre-culture	Test if preculturing on CIM affects up-taking of transgenes, thus affects transformation rate	2	20
T4	Virulence gene	Investigate whether providing Agrobacterium with a plasmid containing virulence gene augments the efficiency of transfer of the T-DNA (transferred DNA)	3	4
T5	Spectinomycin kill curve with no Agro infection	Select which concentration can be used in transformation	6	2
T6	Spectinomycin kill curve with Agro infection	Select optimal concentration for transgenic callus and shoot selection	6	2
T7	Different concentrations Agro	Determine which concentration is effective for gene delivery, but not damage the explants (browning)	4	4

Transformation experiments continued

Experiment ID	Title of experiment	Goal of experiment	# of treatments	# genotypes tested
T8	Different levels of Silwet L77	Determine if/which level of this surfactant helps to Improve transformation frequency	4	4
T9	Different duration of vacuum during Agro inoculation	Determine if vacuum during agro infiltration helps to Improve transformation efficiency	4	5
T10	Different levels of Break Thru-233	Determine if/which level of this surfactant helps to Improve transformation rate	5	5
T11	Duration on CIM after washing	Test whether duration on CIM after washing affect shoot regeneration and transformation	3	20
T12	Different CIM s	Test which CIM will affect shoot regeneration and transformation rates and give highest heritability	4	20
T13	Agro strains	Test different Agro strains efficiency in gene transformation	3	20
T14	Wild Agrobacterium gall induction	Investigate what/how cottonwood genotypes are susceptible to wild Agro, thus they are easy for <i>Agrobacterium</i> -mediated transformation	4	20

Acetosyringone (AS) enhanced GFP callus formation

R7 AS

R21 AS

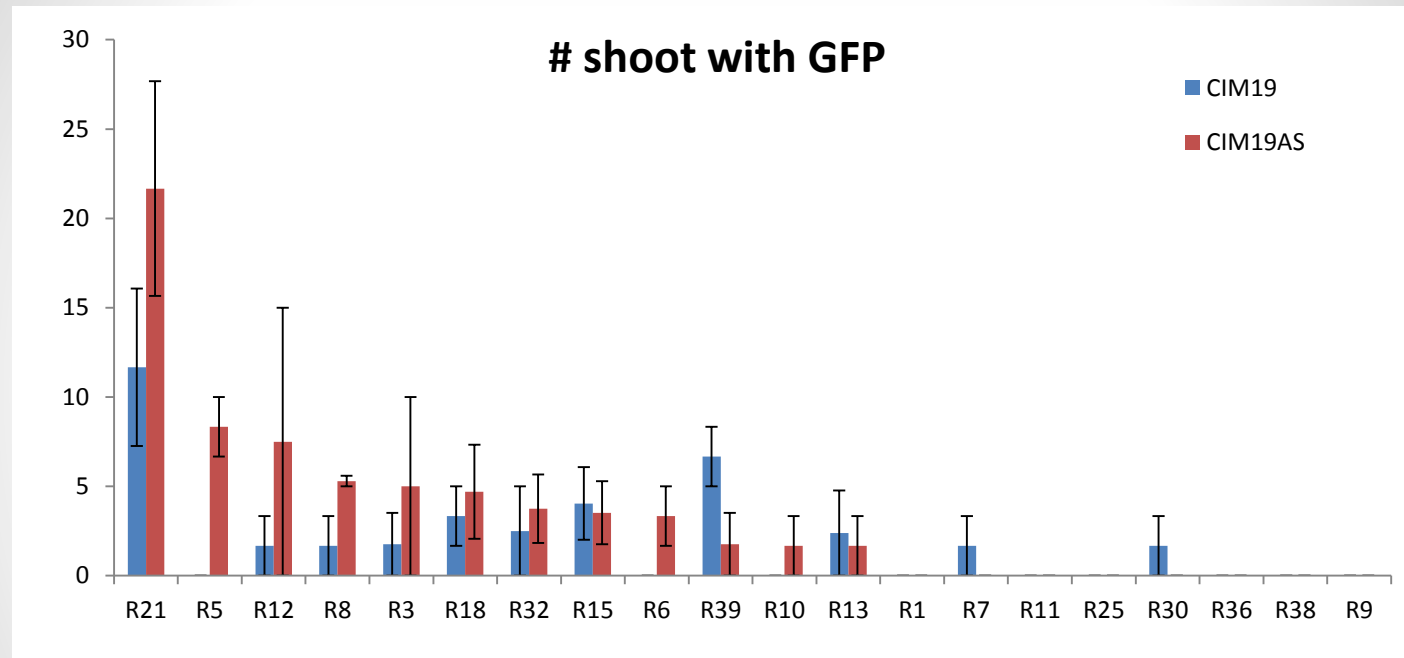

R5 AS

R12 AS

AS also enhanced transgenic shoot formation

R21-2-1 AS

R21-2-1 AS

R6-2-1 AS

R6-2-2 AS

R3-1-1 no AS

R8-1-1 no AS

Crown gall induction under *in vivo* and *in vitro* conditions

- 9 wild *Agrobacterium* strains were provided by Dr. Jeff Chang in Department of Botany & Plant Pathology at OSU
- These wild Agro strains could naturally induce crown gall (tumor) on many plant species
- Our goal is to investigate what/how cottonwood genotypes are susceptible to wild Agro, thus learning if they are suitable for *Agrobacterium*-mediated transformation
- If sufficient genetic variance seen, may employ for GWAS
- Studies ongoing to test H² and best inoculation methods
 - Two candidate strains preliminarily identified in small scale *in vivo* and *in vitro* studies

Callus formation from genotype SKWB24-2 inoculated with 8 wild agro strains and control (water) under *in vivo* vs *in vitro* conditions

In vitro GWAS for callus and shoot regeneration

- Goal is to use the optimal treatment and condition from optimization experiments for over 1,000 genotypes
- Best conditions:
 - Stem explants (4 mm)
 - Two treatments:
 - Direct : 7 weeks in SIM under light
 - Indirect: 3 weeks CIM in dark and 4weeks SIM in light
 - MS medium containing lower salts and 2.5% sucrose
 - 2,4-D 0.01mg/L and BAP 0.5mg/L in CIM and 0.13mg/L TDZ in SIM
 - 12 explants/plate
 - Two plates/treatment/genotype
- Data and images taken:
 - RGB and hyperspectral imaging after 3 and 7 weeks
 - Manual score contamination at week 3 and 7

Sterilization methods used and tested

	Spray with 70% ethanol	1% Tween	Green cure fungicide	70% ethanol	Bleach With vacuum	Bleach at shaking	SuperShock With vacuum	hydrogen peroxide	Sterile H2O
1.	No	5 min	No	5 min	5 min, 15%,	10 min, 15%	No	No	4 times

Examples of bacterial contamination: Wide range of types and size

Examples of fungus contamination

Plates that have more than 6 contaminated explants will be excluded from analysis, and all individual explants scored for presence and extent

Scoring system for callus formation at week 3

Scale	Definition	% Area
0	No callus	0
1	Less than 50% of the original explant area	<50%
2	Greater than 50% of the original explant area	>50%
3	Greater than or equal to the original explant area	≥100%

Scoring system for shoot formation at week 7

Scale	Definition
0	No shoots
1	1-3 shoots
2	4-10 shoots
3	>10 shoots

Scoring system for shoot length at week 7

Scale	Definition
0	0 (no shoot)
1	1-5 mm
2	>5 mm

Good response genotypes

CA-05-01

SLMB-28-1

NISQUALLY

BESC-226

Poor response genotypes

CHWJ-27-2

CHWG-27-2

BESC-869

GW-9857

Future plans

- Use of auxotrophic Agro to avoid wash step in GWAS?
 - LBA4404-thy is kindly provided by Corteva for GWAS transformation. This Agro strain has thymidine synthetase KOd so it dies when explants are transferred to media without exogenous thymidine. It will allow us to skip the washing step in the transformation process and reduce labor and time; thus speeding up the transformation procedure
- Low levels of antibiotics in medium in transformation help to control bacterial contamination
 - Need to assess effect on regeneration
- Retest 3-4 effective wild types Agro for gall induction under *in vitro* condition with longer stem explants and more concentrated Agro solution
 - To conduct GWAS for relative susceptibility to wild Agro based on gall growth
- Use of smaller media cells for regeneration and transformation GWAS?
 - We will test 96-well plates to assess if it can save money on media and allow more GWAS conditions to be assessed (based on chlorophyll and fluorescent reporter signals)
- Expect to begin transformation GWAS in late fall to winter

Publication goals / fall-winter manuscripts

- Regeneration and transformation systems
 - Regeneration optimization
 - Genetic variation and heritability
 - Transformation optimization and heritability
 - Imaging system and data analysis pipeline
- GWAS
 - *In vivo* stem regeneration
 - *In vivo* root regeneration
 - *In vitro* callus and shoot regeneration (direct and indirect)

THANK YOU FOR LISTENING

Phenomics II: Experimental imaging and image analysis pipeline, DEV gene study example/s

Michael Nagle

NSF PGRP advisory meeting

Oct. 3, 2019

Background and overview of phenomics workflow

- *macroPhor Array* used for high-throughput RGB and hyperspectral imaging
- Large volume of data to organize and manage
- Manual scoring of phenotypes and the transition toward automated, high-throughput, objective methods (machine vision, hyperspectral, and the intersection of both)
- Transformation optimization experiments:
 - To demonstrate phenomics workflows (to be refined and used in GWAS)
 - To discuss challenges and plans for transformation optimization experiments themselves

Presentation Overview

- I. Data acquisition and management
- II. Introduction to transformation optimization experiments
- III. Analysis of phenotype data, by phenotyping method
 - A. Manual scoring
 - B. Machine vision data
 - C. Hyperspectral image data
 - D. Integration of machine vision and hyperspectral data

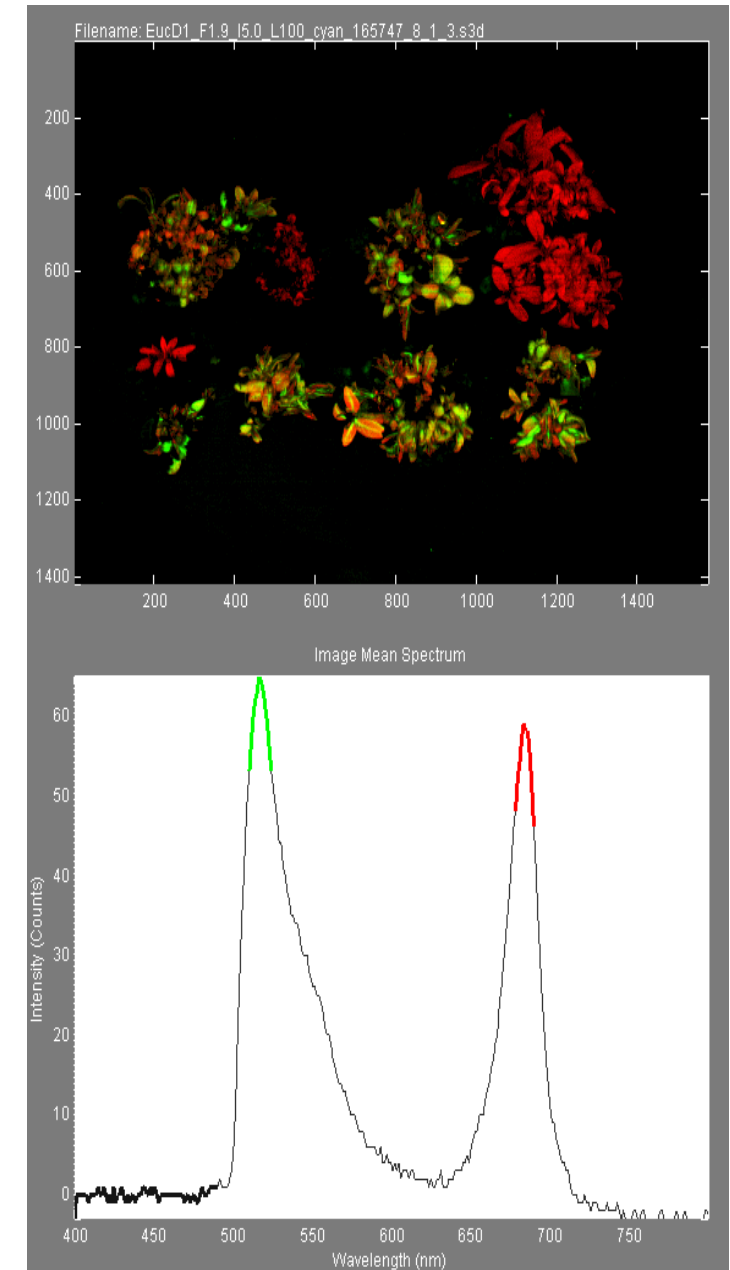

*macroPhor Array*TM

Custom instrument for high-throughput
hyperspectral & RGB imaging

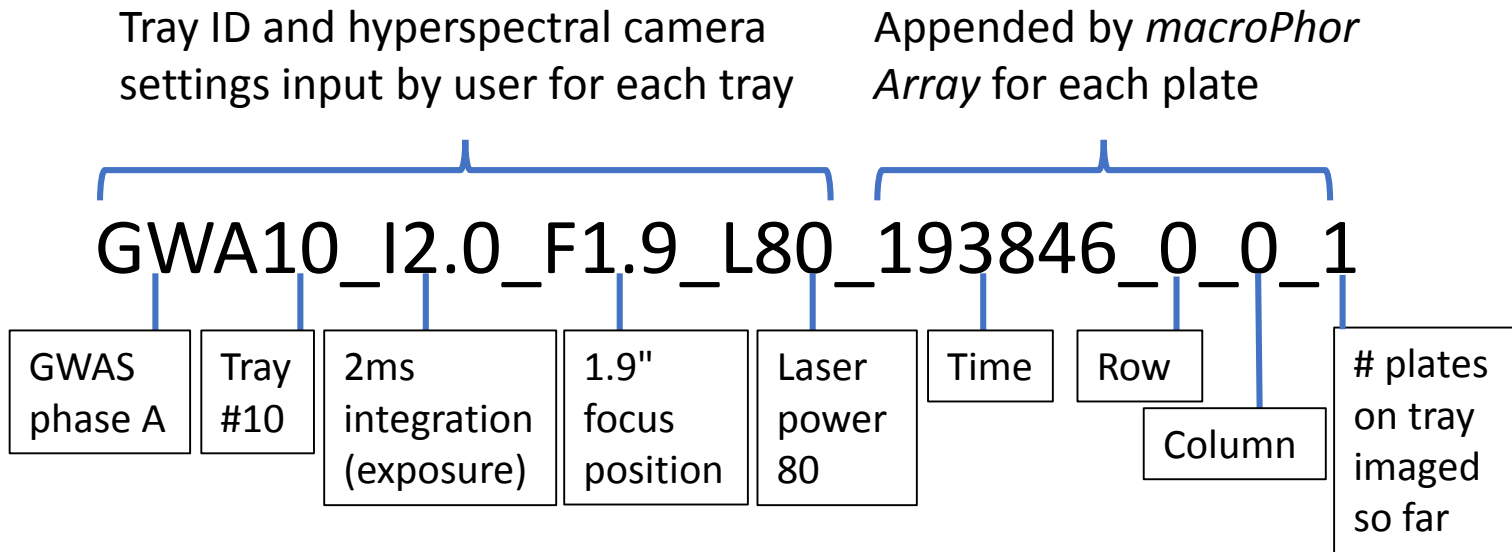

RGB and hyperspectral images are captured

- Hyperspectral images contain a spectrum for each pixel
 - False color applied to certain wavelengths for inspection (right, top)
 - Mean image spectrum shown (right, bottom)
- Standard RGB images
- Ongoing work to align images and integrate hyperspectral analysis with machine vision segmentation of RGB

Unique filenames for each image are connected to biological data through a dictionary

- CSVs contain key linking specific tray and plate ID #s to biological data (e.g. genotype and hormone/gene treatment)
- *macroPhor Array* saves RGB and hyperspectral images for each plate with filenames indicating tray ID and position of plate on tray:

Labeling system to reduce human error risk

- Filename-dictionary scheme requires operator to place plates in specific positions and name trays appropriately
- Potential for labeling system to automate away need for managing filenames and dictionary **or at least provide redundancy**
- Options for labeling systems:
 - 1d barcode (very limited information, e.g. serial number)
 - QR code (attempted)
 - Alphanumeric – currently in use

Size, focus, readability issues lead to errors in reading

Labeling began in GWAS phase 4. Prior, handwritten numeric IDs

Extra redundancy: Dictionary keys **and** IDs
Readable enough with imaging settings for plants

(Automated) high-throughput screening of data for errors

Human error opportunity	Detection method
Crooked plates	Manual sweep probably quickest
Wrong camera settings	<ul style="list-style-type: none">• Check integration time and focus in hyperspectral metadata header (.hdr)• Compare chroma standards to measure laser strength?
Plates placed on wrong tray/slot -OR- wrong tray ID in filename	Compare labels and filenames to keys and IDs in dictionary

- Machine vision reading of labels to speed things up?
 - Time to write code and run vs checking manually?
 - High error rate of machine vision a concern
 - Redundancy of information within labels reduce risk exponentially?

Data storage and backup

- Local copies on hard drives:
 - Failure of two 8TB SeaGate drives (no data lost)
 - All images taken since acquiring imager in Apr. 2018 stored locally indefinitely (to continue?)
- Cloud backups:
 - Team members can search, view, download
 - Current backups for all images on Box
 - Starting Google Drive backups for redundancy (with cloud-cloud sync)

Individual hard drive	Status	Capacity	Cost
Seagate 1	Full	8TB	\$149
Seagate 2	Full	8TB	\$149
Seagate 3	Failed	8TB	\$149
Seagate 4	Failed	8TB	\$149
Western Digital 1	Full	10TB	\$204
Western Digital 2	25% full	10TB	\$204
Internal solid state	Usually ~50% full	4TB	\$600

Presentation Overview

- I. Data acquisition and management
- II. Introduction to transformation optimization experiments**
- III. Analysis of phenotype data, by phenotyping method
 - A. Manual scoring
 - B. Machine vision data
 - C. Hyperspectral image data
 - D. Integration of machine vision and hyperspectral data

In preparation for GWAS of transformation:

Experiments to identify heritable treatments affecting transformation

- Effect of treatment on trait
 - Another heritable phenotype?
 - Unmask QTLs hidden by upstream recalcitrance to transformation/regeneration
- Enhancers of transformation itself
 - Chemical treatments to enhance transformation itself (e.g. acetosyringone, Sil-wet)
 - Agrobacterium strains and virulence (helper) plasmids
- Enhancers of regeneration
 - Hormone treatments (main experiments, for optimization papers, complete)
 - Developmental (DEV) genes as regulators of regeneration (and embryogenesis)
- Relevant both to GWAS project and GREAT TREES industry/academia cooperative on enhancing transformation/regeneration

Background: DEV genes to enhance regeneration... and GWAS of regeneration

- Overexpression of developmental genes (DEV genes) enhances shoot regeneration in plants including Arabidopsis, monocots, soybean, poplar
- Area of research rapidly progressing, expanding to additional genes, species
- Potential for DEV gene overexpression to unmask variation in GWAS

Somatic embryogenesis in recalcitrant maize lines enhanced by overexpression of WUS (co-transformed with GFP)

Effects of DEV genes on regeneration: An additional GWAS treatment

Species	Gene	
<i>Populus trichocarpa</i>	<i>LEAFY COTYLEDON 1 (LEC1)</i>	Studied in Strauss Lab pilot studies, to be studied further in high-throughput screens
	<i>LEAFY COTYLEDON 2 (LEC2)</i>	
	<i>EARLY BUD BREAK 1 (EBB1)</i>	
	<i>WUSCHEL 2 (WUS2)</i>	
	<i>BABY BOOM (BBM)</i>	
<i>Populus tomentosa</i>	<i>WUSCHEL 1 (WUS1)</i>	From Beijing National Forest Academy, to be studied first in high-throughput screens
	<i>WUSCHEL-ASSOCIATED HOMEobox 5 (WOX5)</i>	
	<i>WUSCHEL-ASSOCIATED HOMEobox 11 (WOX11)</i>	
<i>Populus trichocarpa</i>	<i>WUSCHEL 1 (WUS1)</i>	Corteva plasmids
<i>Helianthus annuus</i> (sunflower)	<i>WUSCHEL (WUS)</i>	
<i>Gnetum gnomon</i>		
<i>Malus domestica</i> (apple)		
<i>Vitis vinifera</i> (grape)		
<i>Populus trichocarpa</i>	<i>GROWTH REGULATORY FACTOR 5</i>	Cloning in progress

Pilot DEV studies revealed variables which reduce shoot, GFP phenotypes and/or add noise to data

Variable	How to deal with	
Age of <i>in vitro</i> materials, progressive decline in regeneration ability	Use of only young <i>in vitro</i> materials, or <i>in vivo</i> materials from greenhouse	} <i>Related to transformation methods</i>
Necrosis of leaf explants (seemingly randomly)	Use of stem explants only	
Escape from selection	Switch from kanamycin to geneticin or gentamycin	
Agro culture health (proportion dead cells)	Inoculate all cultures via single colony to starter culture to 50mL culture, simultaneously	
Selectable marker expression, can vary if distance between (promiscuous) promoter and marker varies	Use minimal promoters, consistent spacing in experimental/control plasmids	} <i>Related to plasmid elements</i>
Rate of fluorescent reporter expression	Switch from pRolD:GFP to GmUbi:ZsYellow and GmEFA:DsRed2 (Pioneer)	
Incomplete transgene integration	Use of spacers next to T-DNA insertion sites	
Readthrough transcription/translation of genes outside T-DNA	Use of ALLSTOP elements	

Presentation Overview

- I. Data acquisition and management
- II. Introduction to transformation optimization experiments
- III. Analysis of phenotype data, by phenotyping method**
 - A. Manual scoring**
 - B. Machine vision data
 - C. Hyperspectral image data
 - D. Integration of machine vision and hyperspectral data

Approaches to manual scoring and consequences for modeling

- Manual scoring complete for:
 - Most stem regeneration GWAS data
 - *In vitro* optimization experiments
 - DEV/Vir gene experiments to date
- Discrete scores by plant/explant:
 - Callus size
 - Callus color
 - Pseudo-count of individual shoots
 - Presence of callus/shoot with fluorescent reporter
- Aggregate statistics over whole plates, derived from discrete scores for each explant
 - e.g. proportion of explants with shoot
 - Smooth over intra-plate variation
 - Coerce data into distribution allowing general models w/o significant (?) normality violation
- Generalized models required if significant normality violation unavoidable

Histograms of stem regeneration data (manual scores)

Callus score at week 3

Shoot score at week 3

Callus score examples:

Shoot score examples:

Example analysis of manual score data with modeling (from DEV gene experiment with WUS homologs and superior backbone)

Formula for linear model:

Proportion of explants with callus ~ Gene + Date + Background

Gene treatment	t-value for effect coefficient
<i>P. trichocarpa</i> WUS	0.098
<i>M. domestica</i> (apple) WUS	-3.342
<i>G. Gnomen</i> WUS	-1.595

- Negative results not surprising given:
 - Role of WUS in establishing, maintaining shoot *primordia* specifically ([Zhang 2017 Plant Cell](#))
 - Developmental arrest when WUS expressed w/ strong promoter in *Arabidopsis* ([Zuo 2002 Plant J](#))
- Next: Transient expression?
WUS coexpressed w/ other genes?

Presentation Overview

- I. Data acquisition and management
- II. Introduction to transformation optimization experiments
- III. Analysis of phenotype data, by phenotyping method**
 - A. Manual scoring
 - B. Machine vision data**
 - C. Hyperspectral image data
 - D. Integration of machine vision and hyperspectral data

Machine vision accuracy and precision depends on choice of architecture as well as training and task

Shoot/callus can be divided into multiple classes by color

Accuracy for VGG-19 models:
Fewer classes, better performance

Varying precision/accuracy for different architectures:

- VGG-19 (2014)
- Pyramid scene parsing (2016)
- DeepLab (2018)

In addition to measuring amount of each tissue,
can count separate instances

Machine vision task	Biological trait	Statistical distribution
Semantic segmentation	Proportion of total plant area classified as X tissue	Normal or lognormal after dropping zero values
Instance segmentation	Number of unconnected (or individual) shoots	Poisson? (TBD)

Tissue class	Percent of total area
stem	45%
callus	43%
shoot	12%
Tissue class	Connected components
stem	N/A
callus	9
shoot	5

Semantic segmentation phenotype distributions and approaches to modeling detailed in upcoming GWAS presentation

Presentation Overview

- I. Data acquisition and management
- II. Introduction to transformation optimization experiments
- III. Analysis of phenotype data, by phenotyping method
 - A. Manual scoring
 - B. Machine vision data
 - C. Hyperspectral image data**
 - D. Integration of machine vision and hyperspectral data**

Spectral overlap between fluorescent proteins

Example: DsRed and ZsYellow

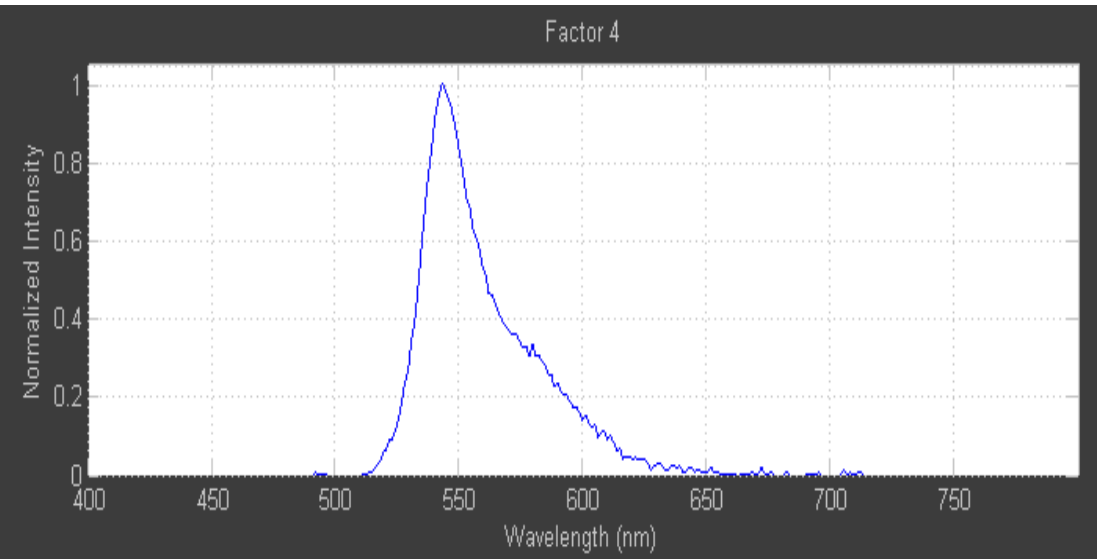

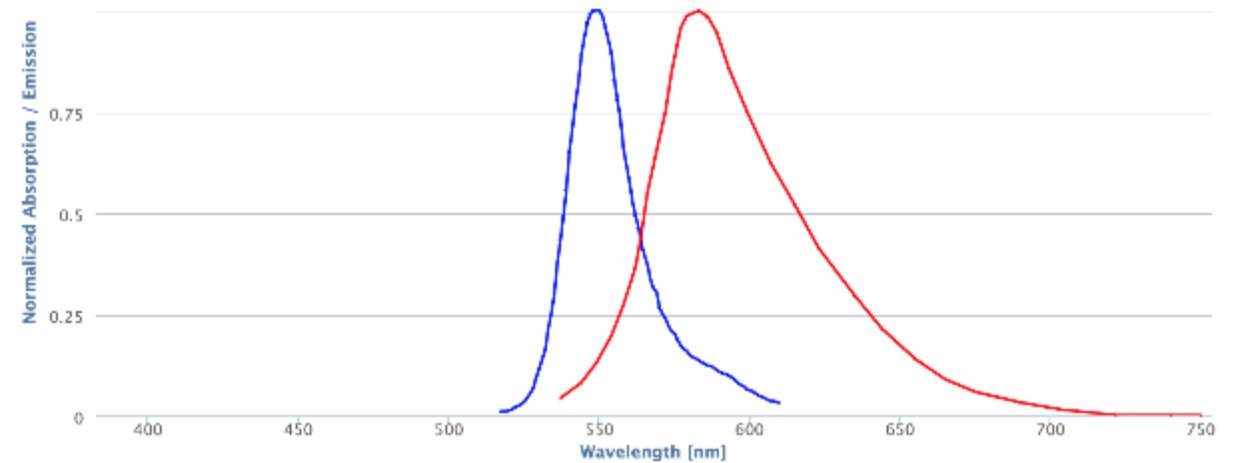

T61 harboring *PtWUS1*
Transformed 5/8
RGB image taken 5/29
Fluorescent image taken 6/14
Plate ID: CT2_13; Explant #12

KemoQuant can deconvolute spectra

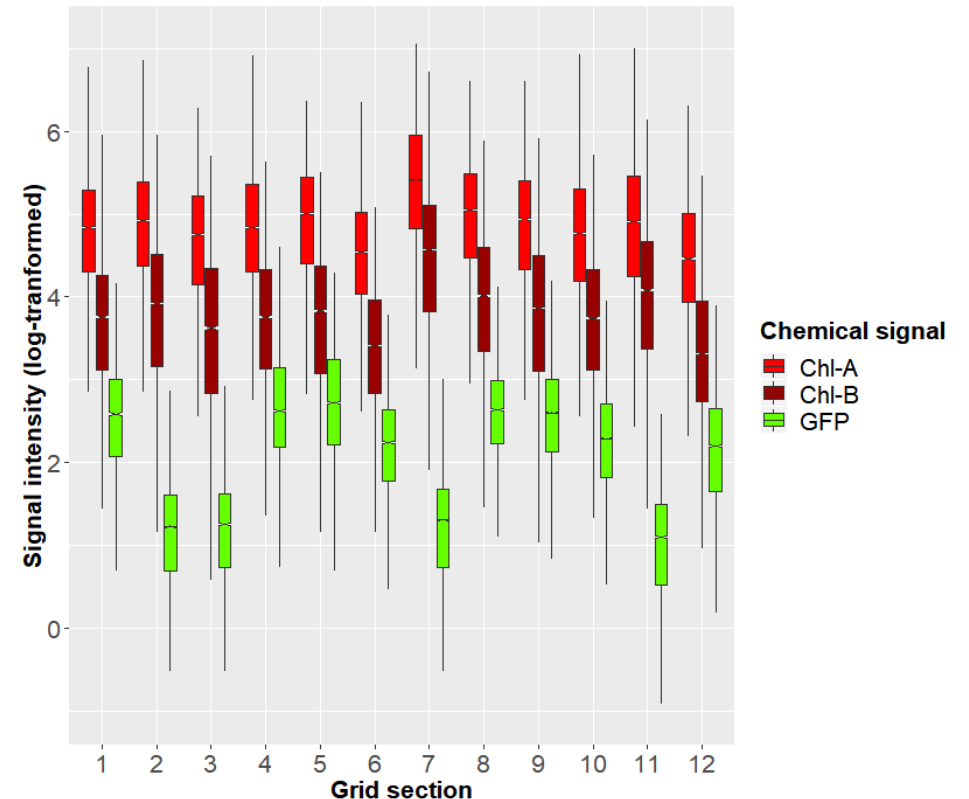

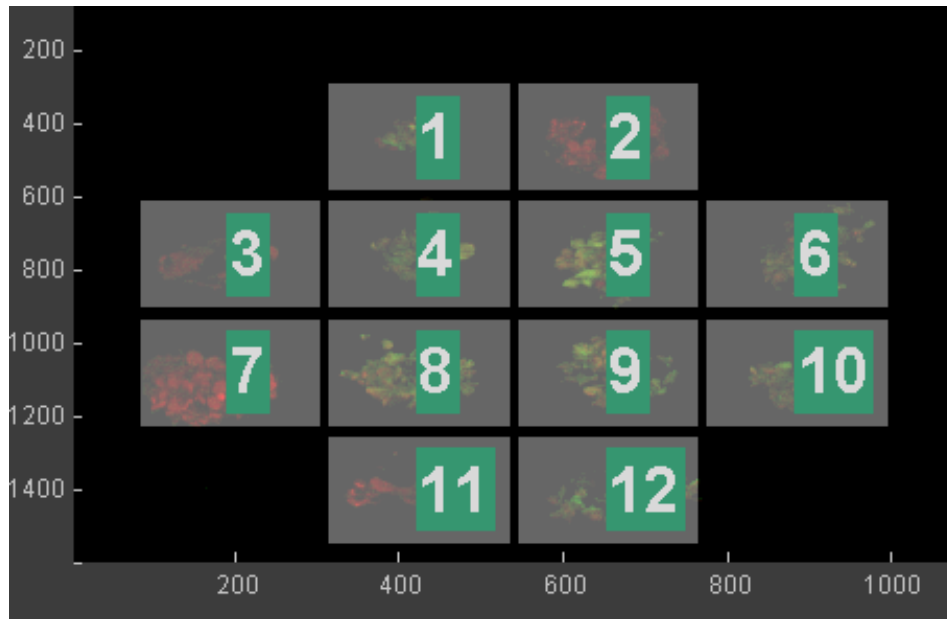

- Multivariate Curve Resolution (MCR) to deconvolute DsRed and ZsYellow (shown)
- Deconvolution of reporter proteins from chlorophylls as well
- PCA option (KemoQuant and R)

Published spectra for DsRed and ZsYellow

Signals for fluorescent compounds are quantified over each grid item (explant)

- CLS of each pixel's spectrum over each fluorophore's emission spectrum
- KemoQuant or R

Hyperspectral data used for transformation optimization and DEV studies – and next for GWAS

Performance of heuristic suggests hyperspectral analysis recognizes transgenic tissue more reliably than human

- Heuristic – a decision rule that is practical and accurate enough
- Potential for macroPhor Array and R code to perform the task of recognizing transgenic tissue
- Attempted heuristic (tested w/ DEV gene data):
Transgenic if enough pixels have enough DsRed signal (from CLS)
 - Apparent power of 80% with 5% false positive rate...
 - Assuming human scores are correct
- Inspection of hyperspectral images after classification by heuristic, comparison to manual scores suggests heuristic much more reliable

Disagreement between heuristic and manual phenotyping

Hyperspectral analysis may outperform as long as overlap controlled for

“False negatives”:

GFP detected by manual phenotyping,
not hyperspectral heuristic

CT1_14_exp7

“False positives”:

Examples of GFP detected by hyperspectral heuristic,
not manual phenotyping

Desire for integration of hyperspectral, machine vision

Not illustrated or currently planned:
Integration of RGB, hyperspectral without first reducing hyperspectral data by regression

Dual approaches to integration of hyperspectral, machine vision

Approach 1: Regression of fluorescent proteins after deep learning

- No deep learning applied to hyperspectral data itself
- Regression to measure reporter signal over pixels labeled by deep learning (from RGB images) as X tissue
- Calculation of total reporter in X tissue

Approach 2: Deep learning including fluorescent signals from regression

- Stack RGB, fluorophore channels, let neural networks learn from all
- To treat transgenic shoot, nontransgenic shoot as separate classes or within a nested class
- Need for ground truth (annotation)

What is total of DsRed test statistics over green area (shoot)?

Beyond R, G, B, extra channels can be added for each fluorescent protein signal (determined by CLS)

Ongoing work to align RGB and hyperspectral channels

- Differences between hyperspectral, RGB channels:
 - Resolution – necessitates rescaling
 - Camera position – necessitates cropping
- Efforts to apply existing alignment algorithms are underway
- Align “green” channels from both image types:
 - Chlorophyll channel from regression of chlorophyll spectrum hyperspectral images
 - Green channel in RGB images

Example attempt to align images

Summary and next steps

- Machine vision and hyperspectral images can offer greater detail, accuracy, reliability than manual scoring
- Desire to implement fully automated phenotyping based on hyperspectral images for future transformation experiments
- For transformation GWAS (or sooner? Transformation experiments?), integration of hyperspectral and machine vision data to obtain scores of reporter protein signal in specific tissues
- Transformation optimization experiments ongoing:
 - Determining optimum chemical treatments to improve zero-heavy distributions of regeneration phenotypes and aid future DEV experiments
 - Preparing for Agrobacterium strain testing (with and without Vir plasmids)
 - High-throughput screen of DEV plasmids with fully automated phenotyping to begin in October

For material discussed, publications and presentations currently planned

Phenotypes	Outlet	Current status	Next steps	Aim to publish/present
DEV gene paper	Plant Cell, Tissue and Organ Culture? New Phytologist?	Preparing plasmids and plant material for Oct. experiment	High-throughput DEV gene screens, making use of insights from transformation optimization	Spring/Summer 2020? Depends heavily on positive results?
Transformation optimization paper		Experiments underway for Sil-wet, selection, more	Complete phenotyping and statistical analysis	Late 2019 or early 2020
Phenomics paper	Plant Phenomics?	Refining phenomic system, particularly: 1. Integration of machine vision and hyperspectral 2. Deep learning model improvement	Annotation for MV training, then workflow deployment	Late 2019 or early 2020
“Phenomic system for imaging and quantification of in vitro plant regeneration and transformation”	Society for In Vitro Biology 2019		Select treatments and begin GWAS (Winter)	June 2020

Phenomics III: Machine Vision Analysis Systems

NSF PGRP Advisory Meeting

October 3, 2019

By Jialin Yuan, Damanpreet Kaur, Michael Nagle, Fuxin Li

Agenda

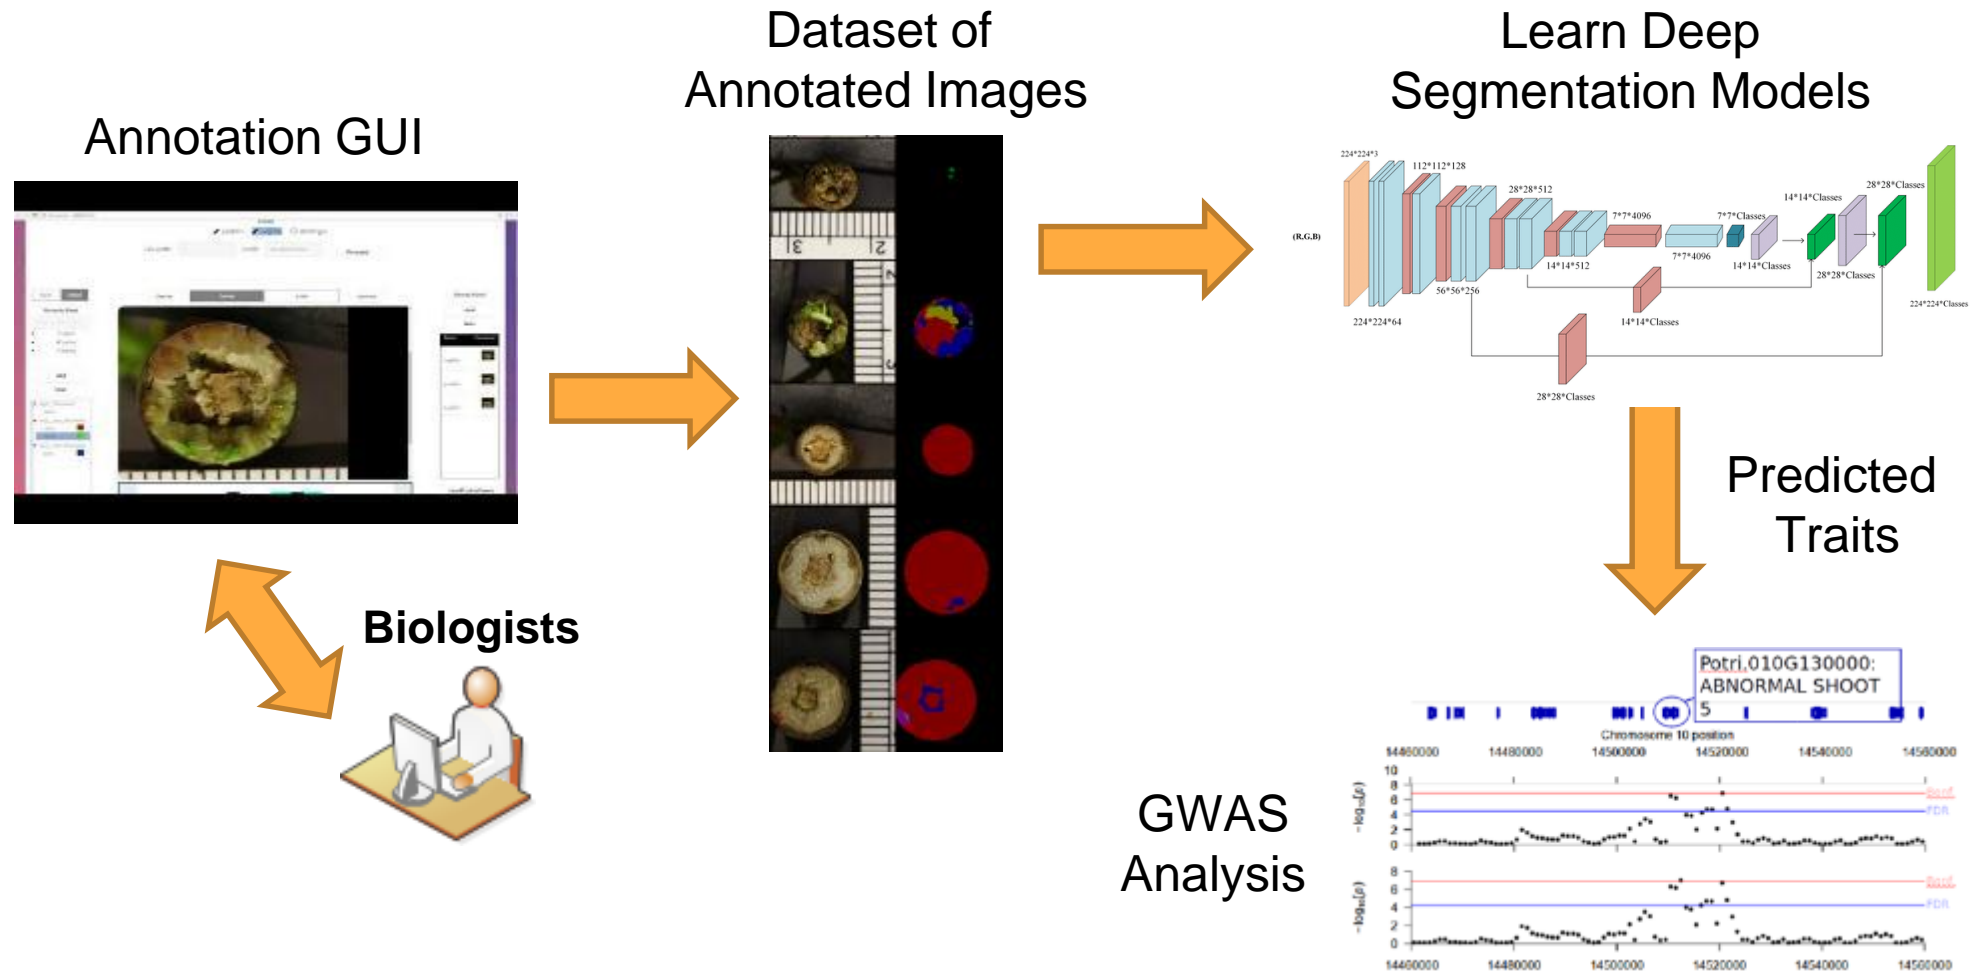

- Annotation GUI
- GWAS analysis with Machine Vision (callus / shoot traits)
- Ongoing technical work on segmentation
- Root growing analysis
- Publication plans and future work

Goal of Image Data Analysis (Slide from 2016)

- Recognizing different types of explants (e.g. shoots, roots, etc.), segment them exactly and count them
- Develop statistics from object recognition and segmentation for GWAS analysis
- Enable users to easily customize “what is an object of interest”

Approach

Annotation GUI

- shoot
- callus
- stem

- obj3_Processed
 - callus
- obj2_Processed
 - callus
 - shoot
- obj1_Processed
 - stem

Action	Thumbnail

posPen	
posPen	

Navigation bar with thumbnails and labels: scale_RED, BESS_GWAS_scale, VNDI_274_05-scale.

Background: Difficulty in Annotation

- Segmentation-level annotation is difficult
 - Most current approaches use polygons
 - Not easy to draw polygons on plants!

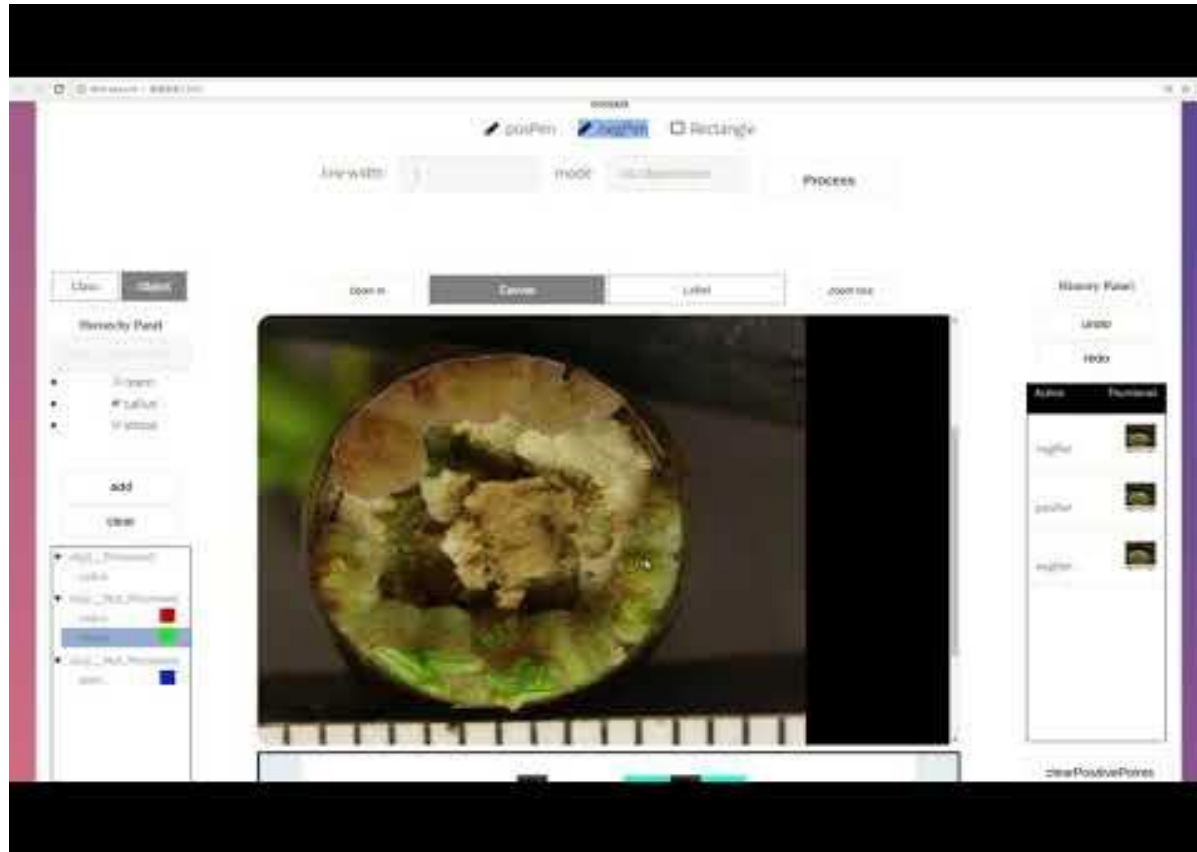

Image Annotation GUI

- Web-based GUI ⇒ No installation, easy to use
- Customizable ⇒ User can specify objects and the properties they have
- Deep interactive object selection^[1] ⇒ Good annotation quality and efficient to use

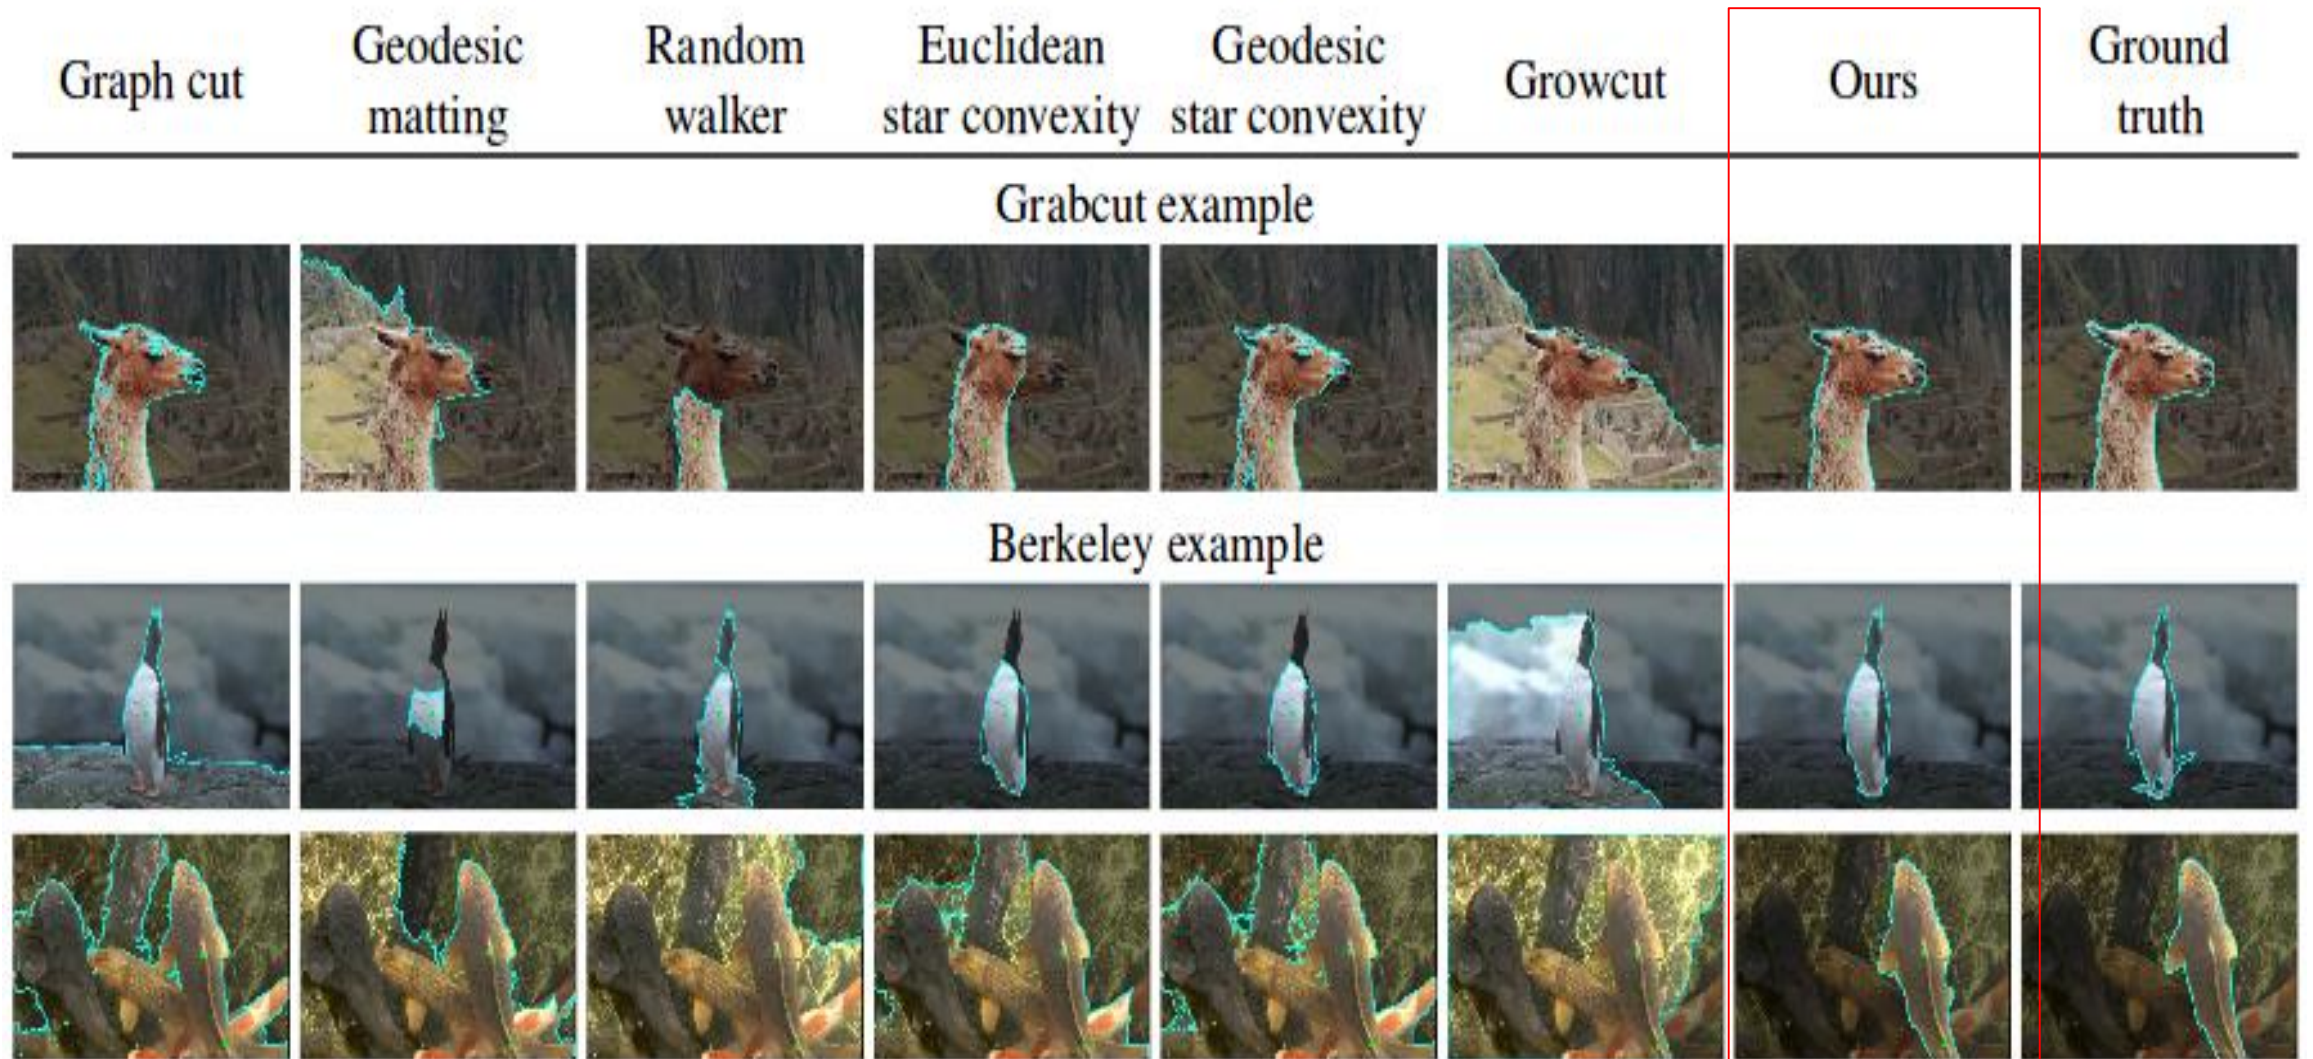

[1] Xu, Ning, et al. "Deep interactive object selection." *CVPR*. 2016.

Deep interactive object selection

Example of selecting an object using the provided user clicks.

Deep interactive object selection

Deep interactive object selection

- The mean **number of clicks** required to achieve a certain accuracy

Segmentation models	Pascal (85% IU)	Grabcut (90% IU)	Berkeley (90% IU)	MS COCO seen categories (85% IU)	MS COCO unseen categories (85% IU)
Graph cut [2]	15.06	11.10	14.33	18.67	17.80
Geodesic matting [1]	14.75	12.44	15.96	17.32	14.86
Random walker [8]	11.37	12.30	14.02	13.91	11.53
Euclidean start convexity [9]	11.79	8.52	12.11	13.90	11.63
Geodesic start convexity [9]	11.73	8.38	12.57	14.37	12.45
Growcut [23]	14.56	16.74	18.25	17.40	17.34
Ours	6.88	6.04	8.65	8.31	7.82

Annotation Tool Timeline

- 2017/1 – 2017/12 Develop the basic annotation tool (V0)
- 2018/1 – 2018/6 Functionality improvements (V1)
 - More than 15 issues fixed, algorithm improvements, V1 is mostly functional
- 2018/6 – 2019/4 Functionality improvements (V2)
 - More than 15 issues fixed, fully functional, used to annotate current dataset
- 2019/5 – now
 - More testing, usability enhancements, preparation for larger-scale deployment

GWAS analysis with Machine Vision (callus / shoot traits)

GWAS Analysis

How well does the plant regenerate?

- Depends on the growth of callus and shoots

Plant Regeneration Experiment

- Annotated 136 images (120 for training, rest for testing) using the annotation tool
- Learned several deep models to predict callus/stem/shoot areas
 - VGG, PSPNet, DeepLab v3+ tried in the process
 - Settled on DeepLab v3+

Callus/Stem/Shoot Segmentation

(Deeplab v3+ [2] Model)

Prediction
Category Label

[2] Chen, Liang-Chieh, et al. "Encoder-decoder with atrous separable convolution for semantic image segmentation." (ECCV). 2018.

Callus/Stem/Shoot Segmentation

(Deeplab v3+ [2] Model)

	Background	Stem	Callus	Shoot	Mean IoU
Training	99.16%	90.37%	90.12%	87.48%	91.78%
Validation	99.17%	73.87%	77.60%	76.47%	81.78%

Model trained using a 80-20 training-test dataset split.

- Training dataset - 102 images
- Testing dataset - 25 images

[2] Chen, Liang-Chieh, et al. "Encoder-decoder with atrous separable convolution for semantic image segmentation." (ECCV). 2018.

Deepplab results

Class Name	Area (%)	No. of Connected components
callus	0.49	5
shoot	0.16	4

Class Name	Area (%)	No. of Connected components
callus	0.43	7
shoot	0	0

Required Annotations

- Estimate the performance on different training dataset sizes
- Less overfitting by increasing the training dataset size
- When does the performance saturate on test dataset?

GWAS analysis: SKAT test

View zoomed to chromosome 10 subsection, aligned to gene track

Association between a known shoot regulator in *Arabidopsis* with computed shoot area

Root Growth Analysis

Week 2

Week 3

Week 4

Interesting traits from machine vision

Leaf size

Stem diameter

No. of roots

Roots' length

Roots' type: bazel or lateral

Pixel size in 'cm'

Interesting traits from machine vision

- Machine vision solution: **segmentation**

Leaf size: area in pixel count

Stem diameter: average width

No. of roots: connections of root to stem

Roots' length: count pixel along root

Roots' type: local background color analysis

Pixel size in 'cm': average width of ruler in pixel

Segmentation on the image

- First level segmentation:
unsupervised
Background | plant | ruler | label

- Second level segmentation:
unsupervised
Background / leaf / stem / root

Segmentation on root growth images

- No annotation is used!

- Segment 'easy examples' using prior-knowledge

- Color
- Location
- Shape

- Train a segmentation network with collected 'easy examples'

- Inconsistent background
- Roots in different color / shape
- Leaves in different color
- Data augmentation from easy examples
 - Rotation
 - Flip
 - Color manipulation

Qualitative results

Leaf size (cm ²)	10.601
Stem diameter (cm)	0.492
# of roots	3
Root length (cm)	[4.264, 3.211, 2.913]
Root type	[Lateral, Lateral, Basal]

Qualitative results

Leaf size (cm ²)	11.377
Stem diameter (cm)	0.553
# of roots	3
Root length (cm)	[5.321, 2.783, 5.175]
Root type	[Lateral, Lateral, Lateral]

Ongoing Technical Work

Interactive Semantic Segmentation

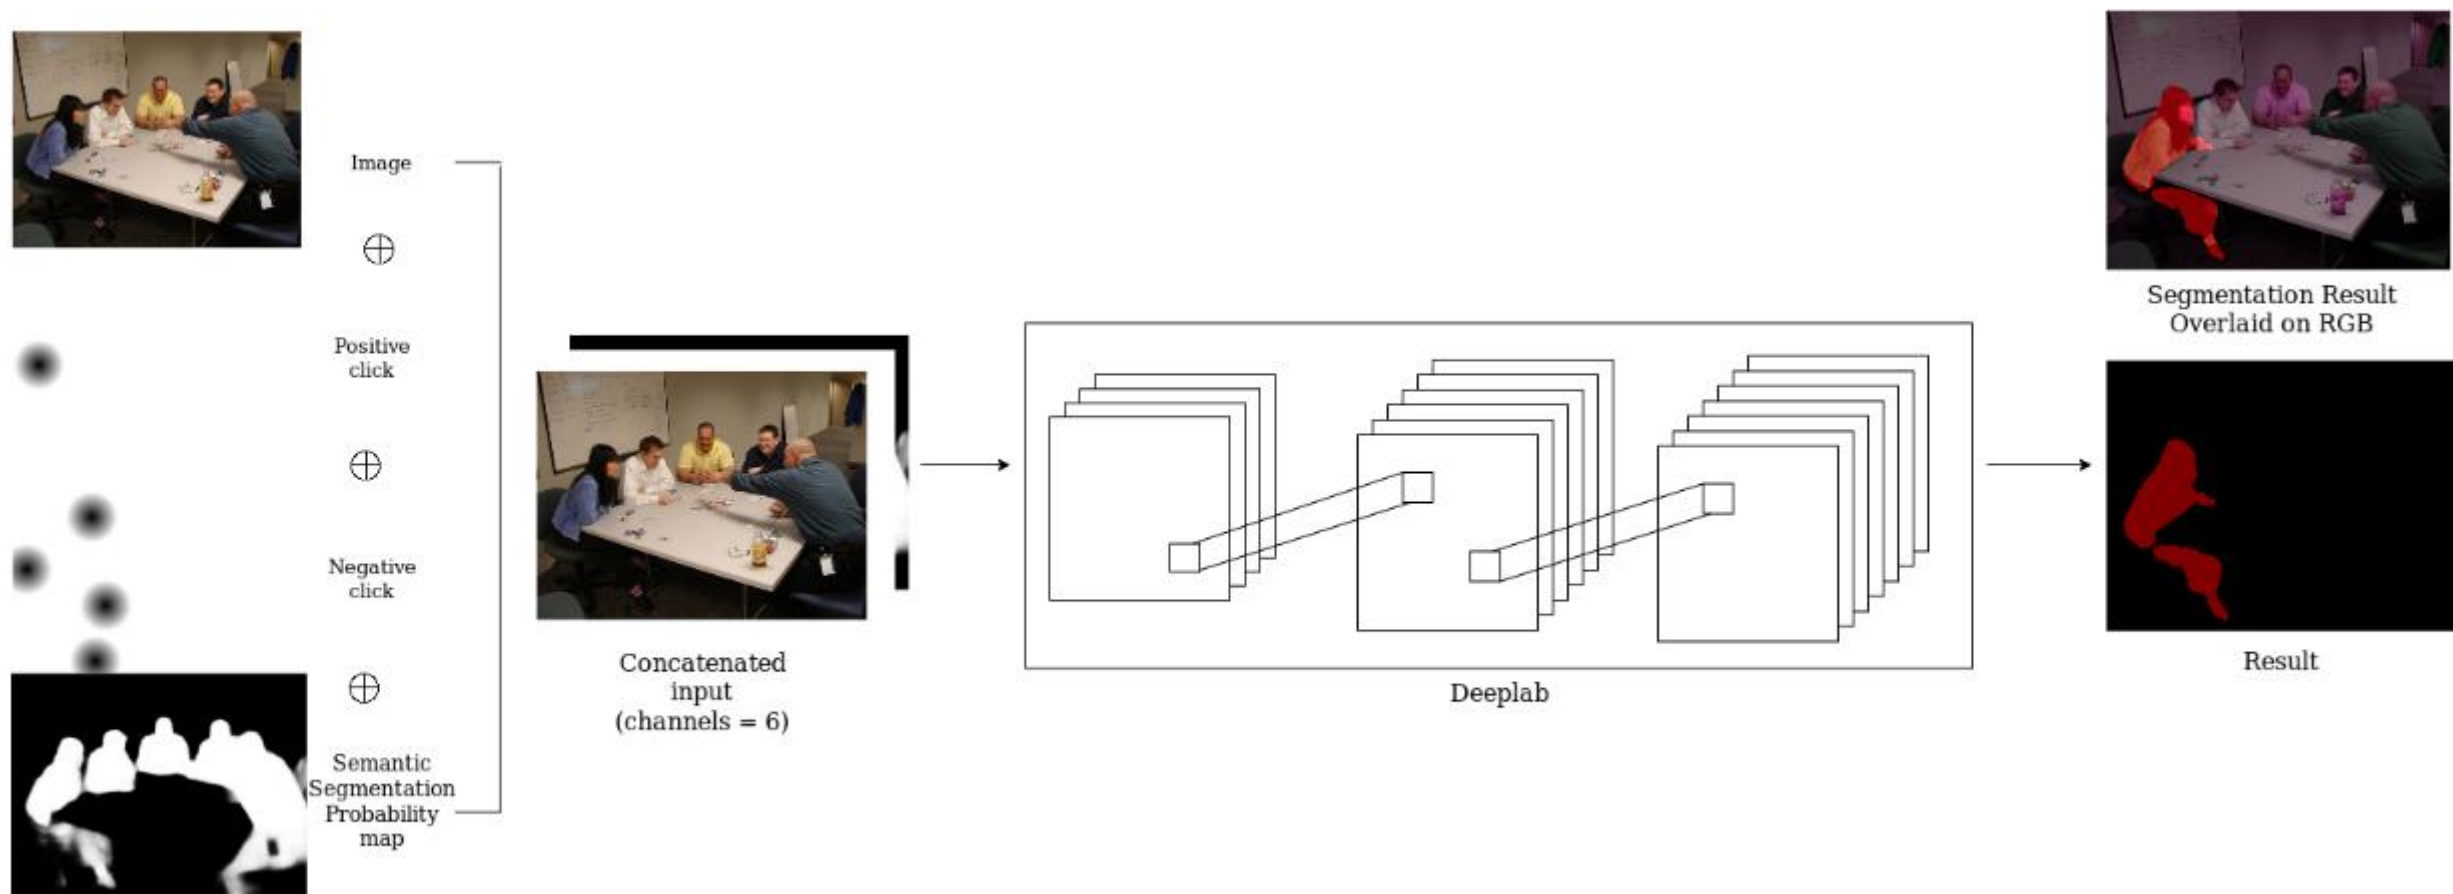

Instance Segmentation

Idea: To understand which object is present in the image at pixel-level.

Semantic-Guided Interactive Segmentation

- Use known semantic segmentation results to guide interactive segmentation
- Semantic segmentation already has good performance, this should make future annotations easier
- Approach: Incorporate semantic prediction results into the deep network for interactive segmentation
- Progress: Good progress on PASCAL VOC dataset, needs integration into the system

Semantic-Guided Interactive Segmentation

Semantic-guided Interactive Segmentation Results

Semantic-guided Interactive Segmentation Results

Incorporating Semantic-guided interactive algorithm into the Annotation system:

- The new algorithm will help in improving the -
 - Efficiency
 - Performance of the annotation system
- Reduce the interactive effort on the user part
 - Useful for plant scientists as it requires minimal user input while annotation

Instance Segmentation

- What is Instance Segmentation?

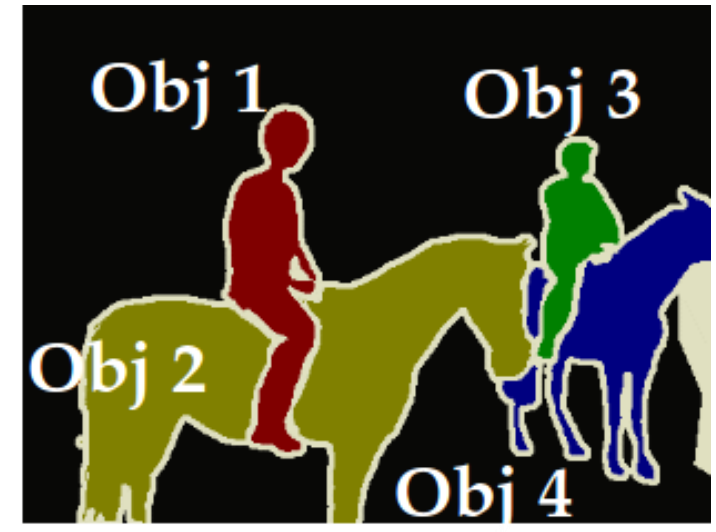

Image

Category Label

Object Label

From Proposals to No Proposals

- One stage segmentation approaches
 - Significant amount of redundant computation
 - Bottom-up process is difficult to become real-time

Visual of top 50 proposals

Ground truth annotation

From Proposals to No Proposals

- Predict a surrogate objective
 - Post-processing from the prediction
 - FCN can directly predict surrogate without proposals
 - Those surrogates have issues

Bai & Urtasun 2017

Uhrig et al. 2016

From Proposals to No Proposals

- We proposed to directly predict the instance label
 - Relax the labels to be continuous-valued
 - Directly predict **real-valued** instance labels as a deep network

Input Image

Real Valued Labels

Current Results on PASCAL

1. **Instance Segmentation (submitted once to ICCV 19)**

Conference: CVPR

Timeline: November '19

2. **Semantic-guided interactive segmentation**

Conference: CVPR

Timeline: November '19

3. **Annotation System**

Journal submission (a plant phenomics journal)

Future Work

1. Annotation System

By 2019

- a. Further work on improving the GUI, adding shortcuts and making it more user-friendly
- b. Improve documentation and user guide on the annotation GUI, release it to the public
- c. To be solved: GPU resources?

Spring 2020

Incorporate the semantic-guided interactive segmentation algorithm for the annotation system

2. Hyperspectral Image System

By 2019

Align FP hyperspectral matrices with RGB image for all grid types

Future Work: Automatic Trait Analysis

- One lesson learned from the entire effort is that training networks is not that straightforward
 - Deep models require significant amount of parameter tuning (a dedicated person tuning for 1-3 weeks, depending on experience)
 - For the goal: fully automate the trait analysis (including model training), several improvements needed
 - Automatic connection to a cloud engine with GPU resources
 - AutoML for tuning the parameters
 - A fee model to accommodate computational costs and software engineering work to setup
 - Additional funding probably needed to achieve that goal
 - Currently starting a Capstone project

Future Work: Hyperspectral Imaging

- We realize that it may not be easy to annotate hyperspectral images via segmentation
 - Some proteins are too simple (e.g. GFP) where partial linear regression or PCA followed by simple thresholding is sufficient
 - Others are too complicated and scattered in high-dimensional hyperspectral data, making it hard to label
 - Maybe necessary to utilize longitudinal analysis to obtain labels (e.g. plant growth after several weeks)
 - How to best integrate hyperspectral data and automatic trait analysis is an unresolved problem

Thank you!

GWAS pipeline and results

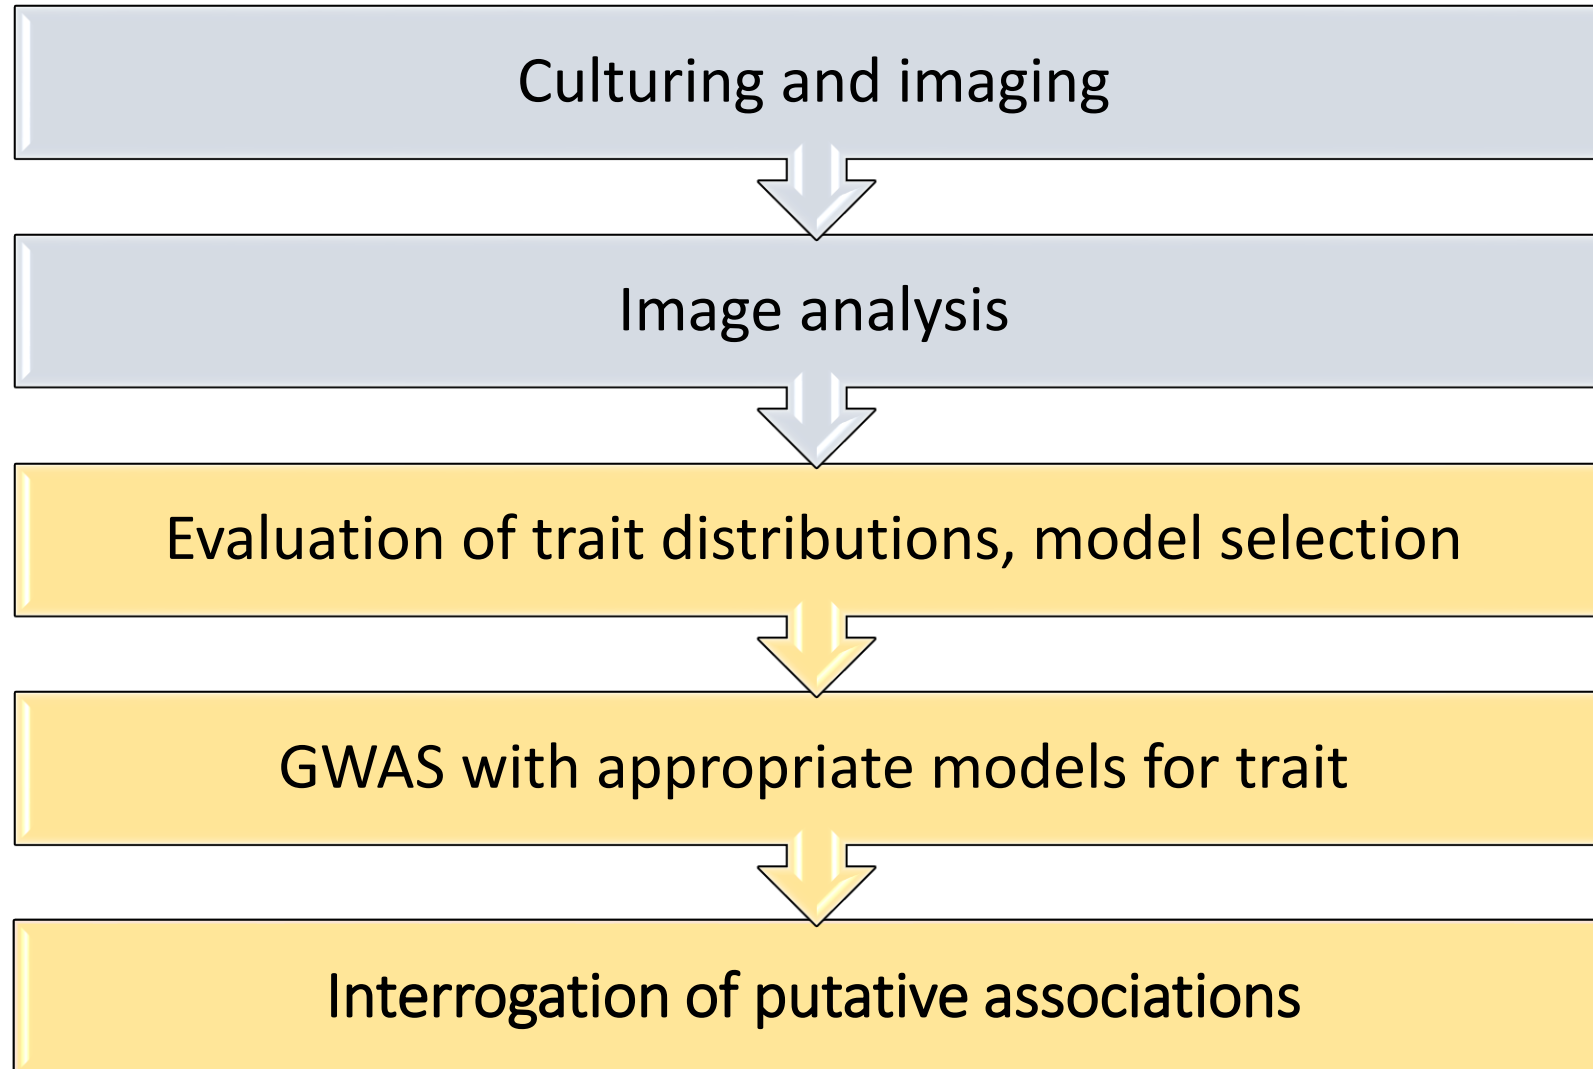

Michael Nagle

NSF PGRP advisory meeting

Oct. 3, 2019

From phenotyping to GWAS and beyond

Overview of GWAS and post-GWAS methods

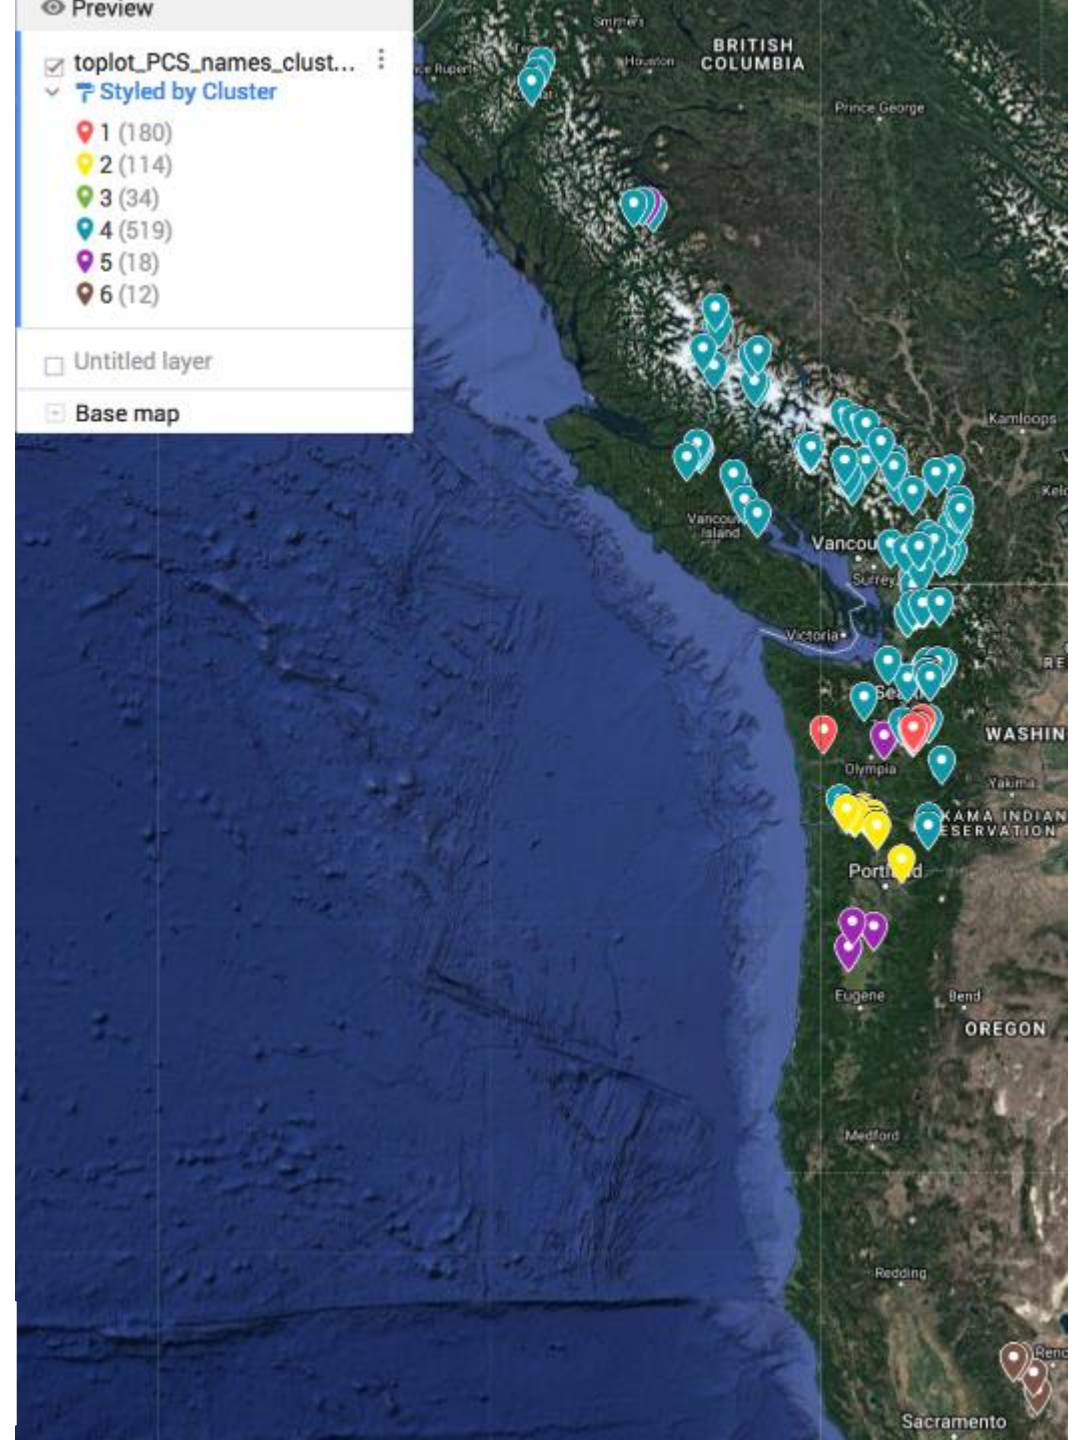

- Appropriate modeling tool depends on distribution of phenotype data (and transformation, if any)
- Resampling: Calculate p-values with true null distribution, rather than depending on approximation to a common distribution
- Desire to resample efficiently over large SNP set motivates use of:
 - GWAS methods combining SNPs
 - High-performance computing
- After GWAS: Is a role for genes implicated by GWAS also supported by evidence from literature, transcriptome, interactome, mutant studies?

Genomic resources for *P. trichocarpa* open doors for genetic discovery

- Current SNP set (released 2016) from Oak Ridge National Laboratory's Bioenergy Research Center
 - 882 genotypes
 - Diversity from California to British Columbia
 - ~28M SNPs
 - ~40x coverage
 - Single reference genotype (Nisqually-1)
- To come: additional genotypes and pan-genome

[Interactive Google Earth map of GWAS population, PC clusters](#)

Ongoing GWAS pipeline testing and refinement using stem regeneration GWAS data

- Project includes GWAS of *in vitro* regeneration, stem regeneration, rooting, transformation and more traits
- Stem regeneration:
 - Wound gives rise to callus, shoot
 - Cytokinin (TDZ) on stem tip encourages regeneration

Plant images segmented by machine vision to provide statistics for use in GWAS

Machine vision
segmentation of images by
tissue class

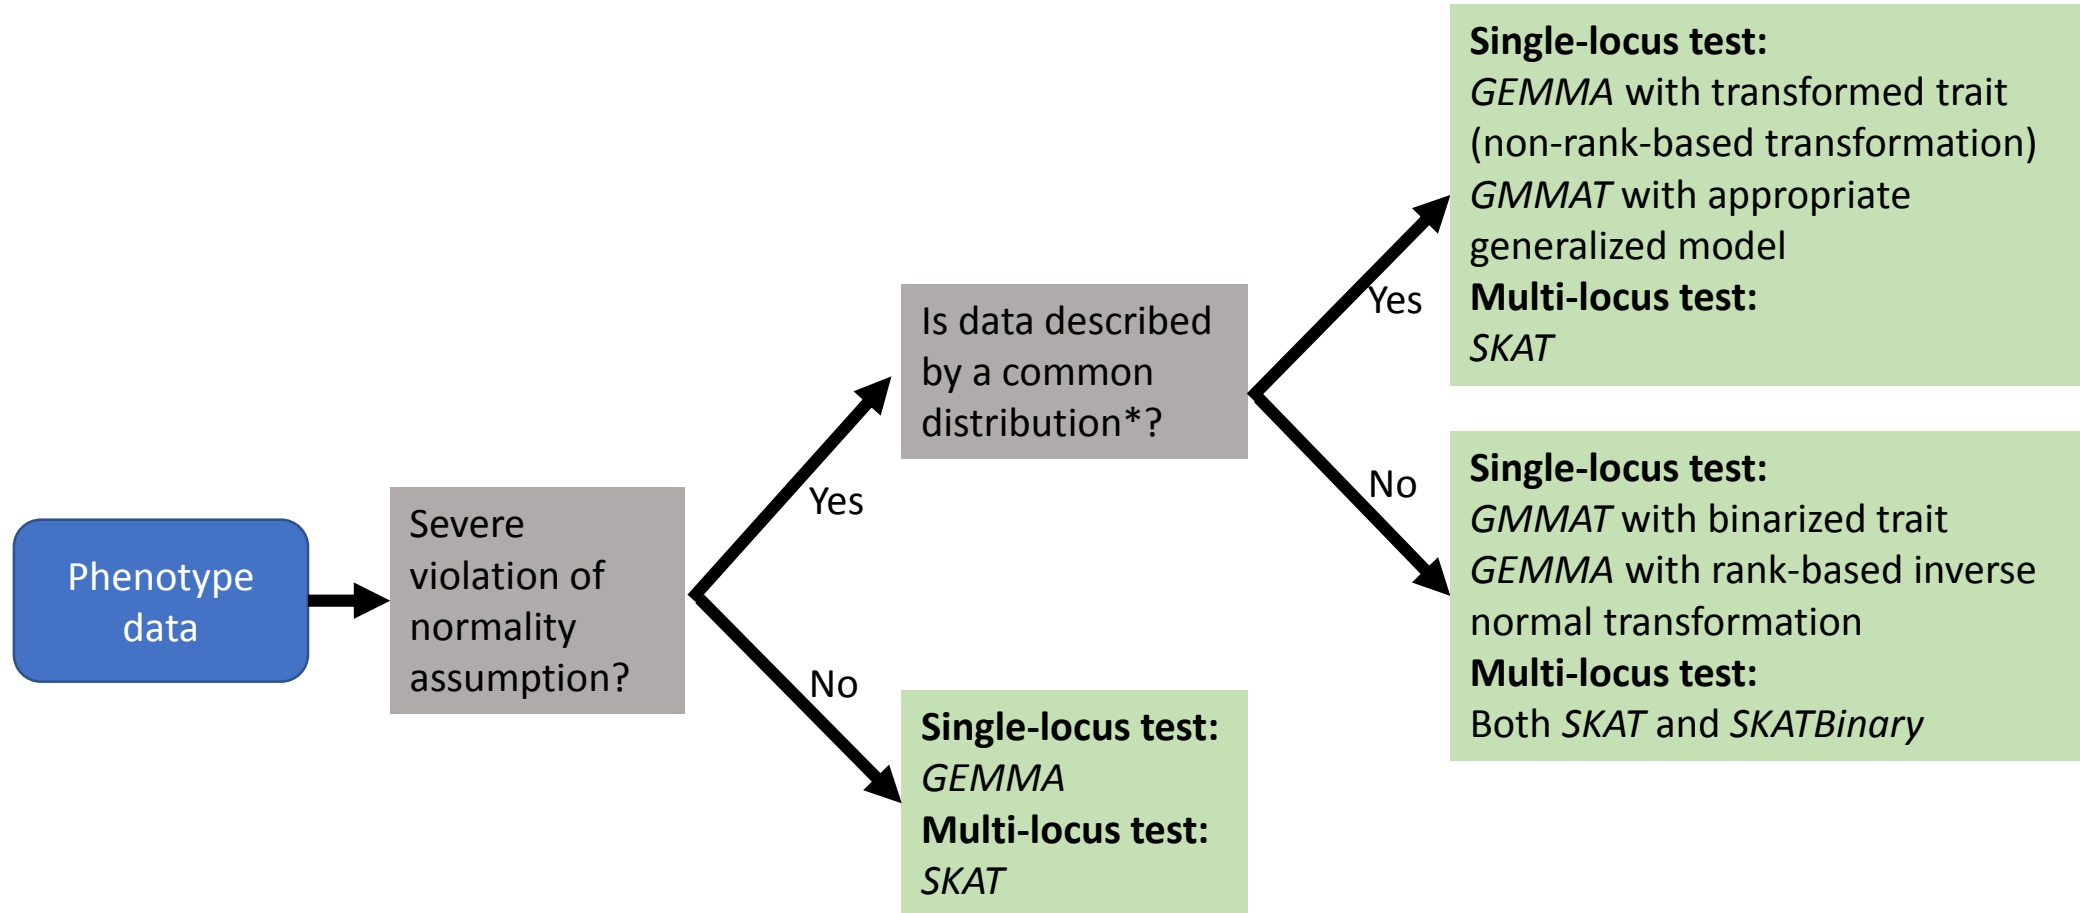

Calculations of area
statistics for each tissue
class

Tissue class	Percentage of total area
stem	45%
callus	43%
shoot	12%

Into GWAS

Current GWAS workflow

*with support in generalized modeling tools in R

We have attempted/performed analyses using these ten GWAS tools

Tool	Type	Notes
PLINK	General linear model	Model phenotype as function of SNPs and PCs
TASSEL5		GUI, not written for large SNP sets
GENESIS	Mixed linear model	Assumes variance of SNP effect coefficient is the same for every SNP
EMMAX		
GEMMA		
GMMAT	Generalized mixed linear model	Can build models for certain non-gaussian distributions
SKAT	MLM with kernelized SNP-sets	Tests user-defined SNP groups
Farm-CPU	Alternating mixed/unmixed model	Trouble with large SNP sets
BOLT-LMM	Bayesian mixed linear model	Adds no SNPs to model since heritability calculations require larger, more homogenous population
MLMM		
FaST-LMM	Mixed linear model	Fast GWAS method that is well-established and exact

Key:

Producing results for full SNP data

Problems due to data input

Linear models in GWAS:

Is there an association between allele and trait?

$$y_i = \mu + G_i\beta + \varepsilon$$

G_i : genotype variant
(0, 1 or 2 copies of alt. allele)

Association between trait and #
copies of alternative allele

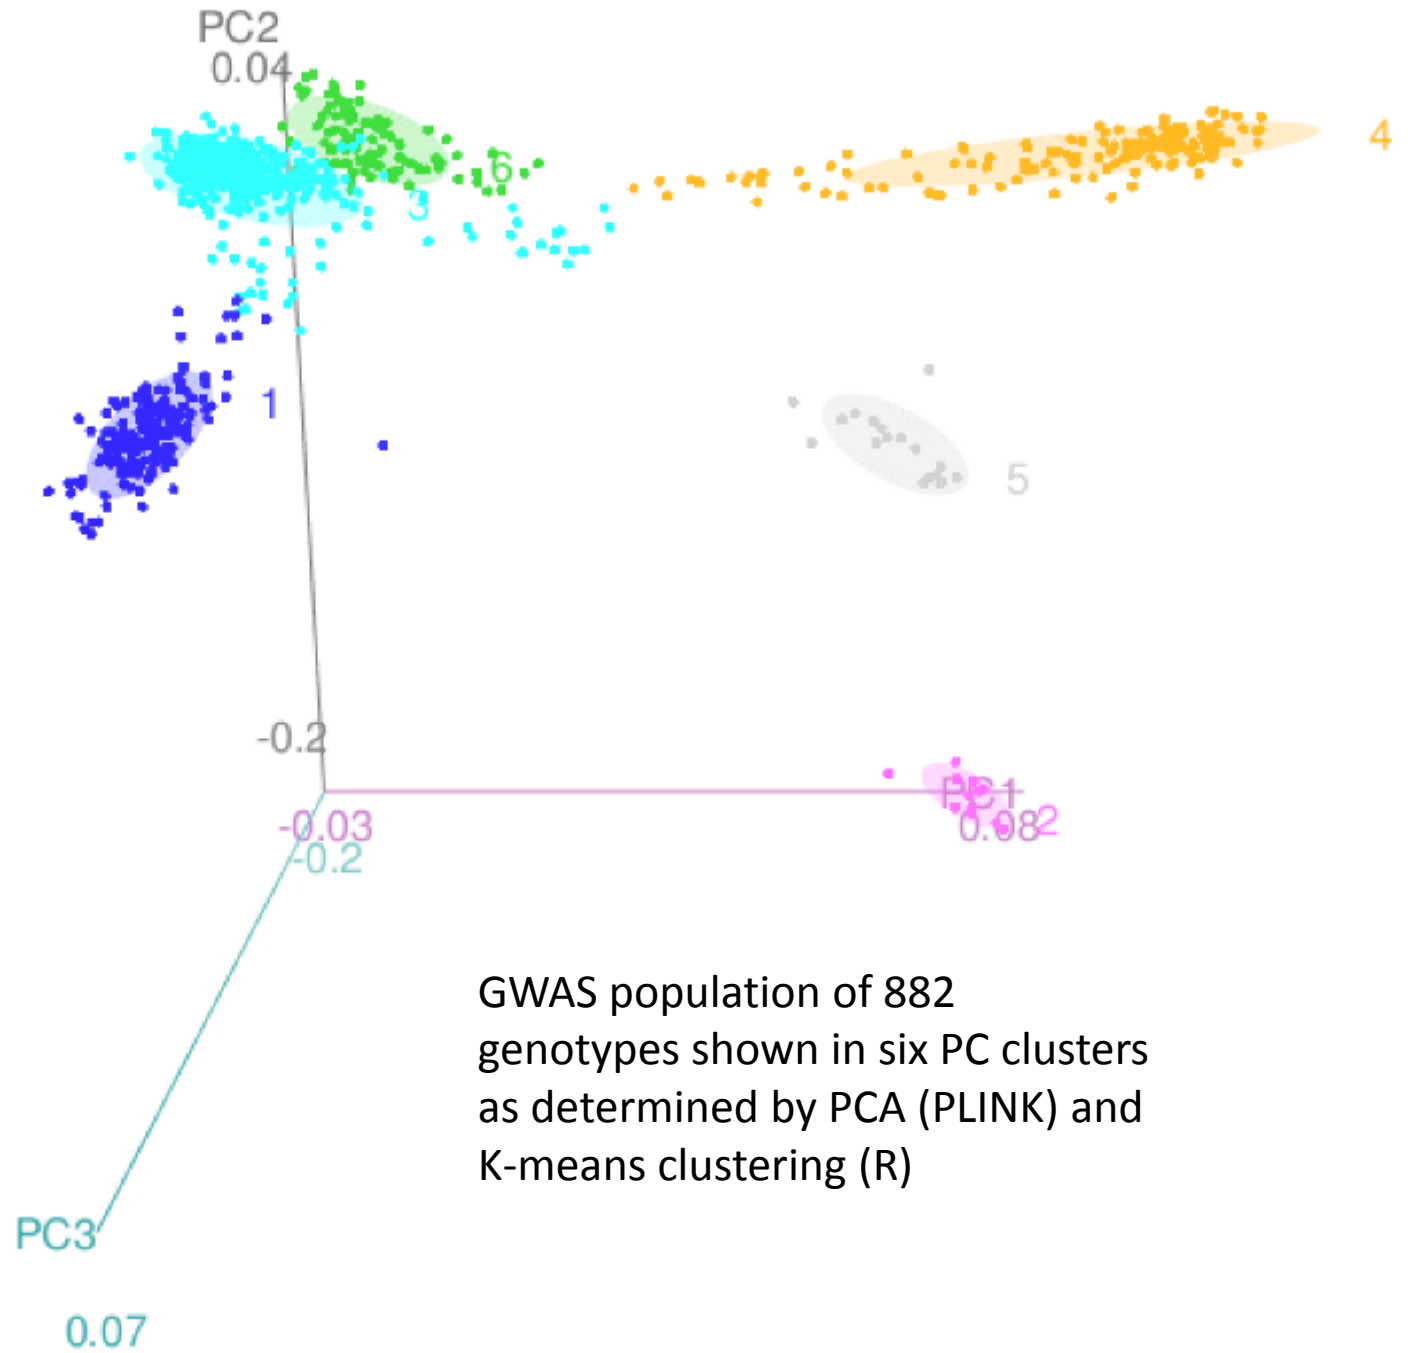

graphics from UWISG GWAS workshop Aug '18

Note: Dominance models are occasionally used in GWAS

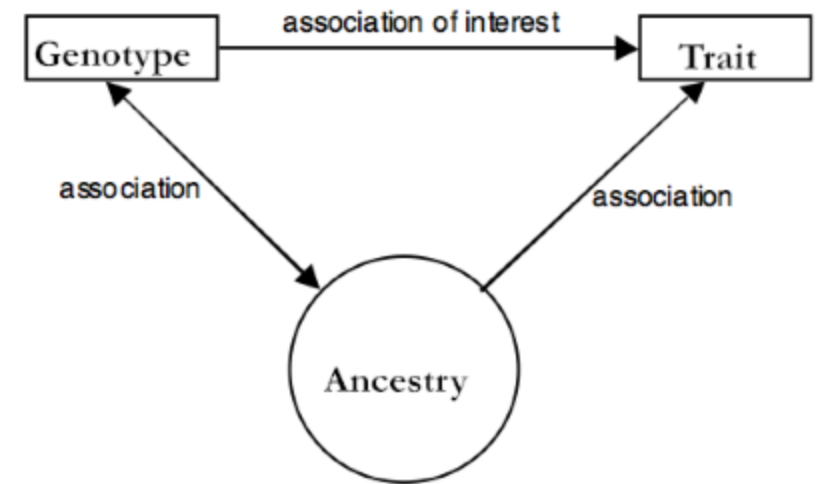

Six clusters of closely related genotypes across three principal components (PCs)

Controlling for population stratification

- Why an association between trait and SNP? Causal association, or confounding factor of population stratification?
- Approaches to control for stratification:
 - A. Multiply p-values by a relatedness coefficient
 - B. Split GWAS population into subpopulations
 - C. Include population structure in model
 - i. Principal components
 - ii. Kinship matrix (in mixed model)

[UW Institute for Statistical Genomics](#)

- Overcorrection in highly stratified populations with rapid linkage disequilibrium decay? Alternatives?

Adherence of traits to normality assumption?

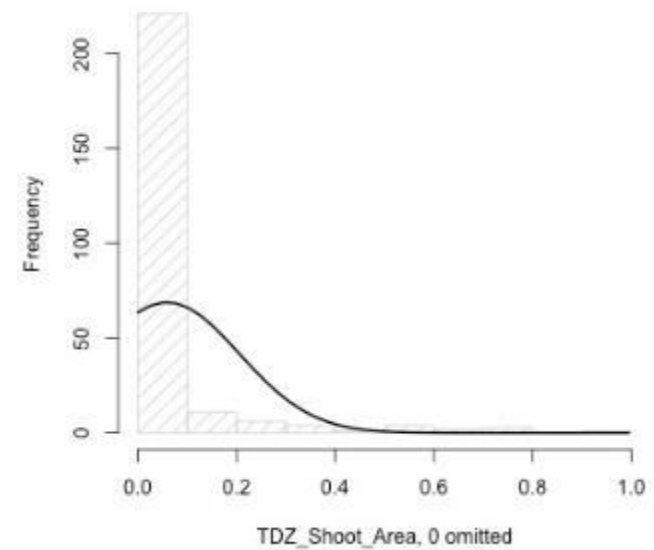

Proportion of stem with callus

Proportion of stem with shoot

Zero values not shown on histogram:
30 for callus
336 for shoot
(out of 590 total)

Adherence of traits to normality assumption *after log transformation*?

- Zero values dropped before log-transformation
- With log-transformation, improved adherence to normality assumption for shoot area

Zero values not shown on histogram:
30 for callus
336 for shoot
(out of 590 total)

Proportion of stem with callus
(log-transformed)

Proportion of stem with shoot
(log-transformed)

Reducing and coercing data to normality by dropping zeros and log transformation

- Multiple testing corrections:
 - Bonferroni (red)
 - FDR (blue)
- Alternatives to log transformation...

Note: Phenotype data used is from PSPNet with 126 training samples (Jan '19)
– soon to come better models, more training data

For perfect match to normal distribution, rank-based inverse normal (RB-INV) transformation

QQ-plot of shoot area phenotype after RB-INV (but before dropping zeros)

RB-INV transf. without zero values omitted (590 genotypes)

RB-INV transf. with zero values omitted (254 genotypes)

PLINK results for callus area (no transformation)

Will more genotypes, increased power, will produce results surviving correction?
Is phenotype normal enough for this model to be valid?

Mixed effect linear models with kinship matrices more conservative than PCs alone

- Kinship matrices capture relationships on finer scale than PCs
- With kinship matrix in model, evidence from closely related individuals is downweighted
- Same kinship matrix can be used for all GWAS methods discussed except
 - PLINK (option not available)
 - SKAT and FaST-LMM (produce their own meeting req.)

Kinship matrix for poplar GWAS population calculated by proportion of SNPs identical-by-sequence (IBS)

Generalized Linear Mixed Model Association Test (GMMAT) offers flexibility

- Generalized linear mixed models (GLMM) for modeling data where errors do not follow normal distribution
- Link function: Model a function of y instead of y
- Flexibility in choosing family of distribution

2018

Although SKAT most commonly used in human GWAS, has been used in poplar

- Limited statistical power of GEMMA, other single-locus methods
- Rationale for using SKAT: Greater statistical power comes with ability to
 1. detect effects of rare SNPs
 2. test combined SNP effects

First preliminary results with SKAT shown for callus

(Phenotypes from VGG19 with 590 genotypes, 88 training samples)

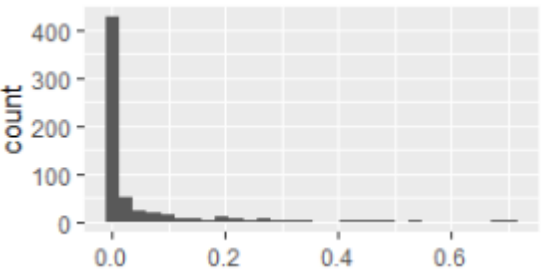

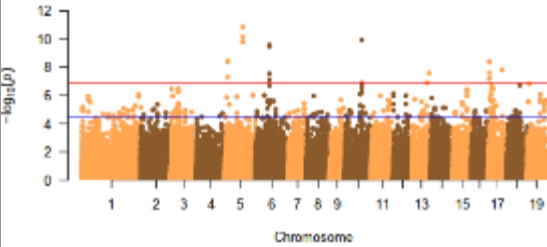

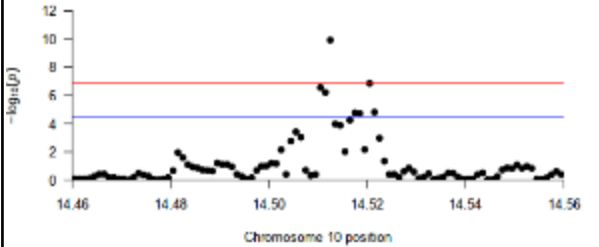

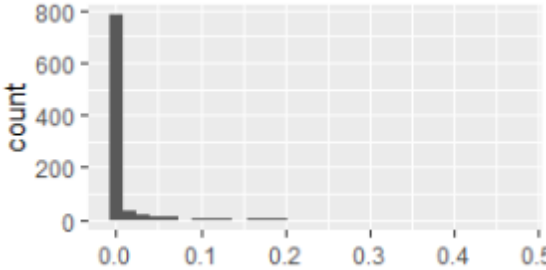

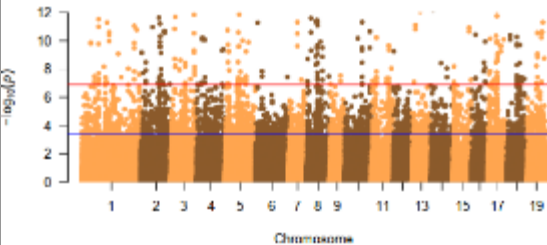

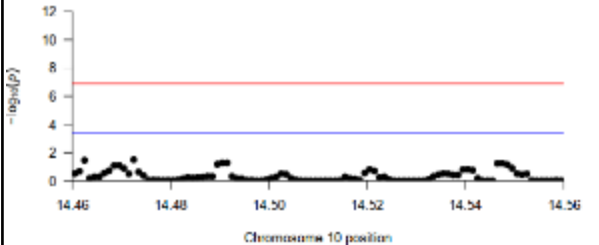

Results for shoot: Many highly significant SNPs are found in intergenic regions or uncharacterized genes

(first SKAT model shown – VGG19 with 590 genotypes, 88 training samples)

Wildly different results for SKAT with two phenotype datasets

Model	# Training samples	Mean IoU	# Testing samples	Distribution of phenotype values	Whole genome view	View zoomed to segment of Chr. 10
VGG19	88	79.0	590	 <p>Proportion of area classified as shoot</p>		
PSPNet	126	80.6	882	 <p>Proportion of area classified as shoot</p>		

Multiple-testing corrections

- Bonferroni adjustment
 - Depends only on number of tests and confidence level (usually 0.05)
 - Assumes independence of tests
 - Correlations between phenotypes, and between SNPs in linkage disequilibrium
 - Adjusted Bonferroni for $N(\text{effective})$ independent SNPs – less conservative
- False Discovery Rate adjustment (Benjamini-Hochberg)
 - FDR threshold depends on distribution of p-values and varies between traits... many producing no FDR-significant p-values and no ability to calculate a threshold
 - Usually less conservative than Bonferroni, with extent depending on trait

Resampling to allow relaxation of normality assumption

- An alternative to transformation or the use of GLMMs
- Resampling by permutation:
 1. Scramble phenotype data
 2. Repeat test X times, list p-values of effect of SNP on (randomized) phenotype
 3. Where does p-value for true data fall in null distribution?
- Adaptive resampling (AR) to reduce computational burden
Runtimes for AR with shoot phenotype shown:
 - ~100 CPU hours for SKAT
 - CPU years for single-locus methods

Little change from resampling

Potri.010G130000: ABNORMAL SHOOT 5

Position on Chromosome 10 (Mb)

14.46 14.48 14.50 14.52 14.54 14.52

Without resampling

Empirical p-values found by resampling

According to some sources, resampling may be used as substitute for multiple testing correction

- Correlations between SNPs are preserved during resampling (genotype data not shuffled – only phenotype data)
- Resampling control for familywise error-rate and abolish need for multiple testing correction for SNPs?^{1,2}
- Examples from human GWAS³:
 - "Empirical p-values < 0.017, reflecting Bonferroni correction for 3 independent tests (one per brain region): $\alpha = 0.05/3$, were considered to represent significant association."³

Producing results for full SNP data

Problems due to data input

Developing capabilities for resampling in single-locus GWAS

- Requirement 1:
Efficient GWAS code –
FaST-LMM built for high-throughput GWAS
- Requirement 2:
Public high-performance cluster computing resources
- Requirement 3:
Code for parallelization of FaST-LMM with resampling
(using Apache Spark or similar framework)

FaST-LMM for high speed and accuracy

- Mathematical approach:
 - Algebraic transformation to find uncorrelated SNPs, use these to build kinship matrix
 - Use of a kinship matrix made from M SNPs lower than N genotypes allows for models to be built more quickly
- Consequences of FaST-LMM innovations:
 - Order of magnitude faster than inexact method EMMA, nearly 2 orders of magnitude faster than exact method GEMMA
 - Said to produce same results as GEMMA
- Released in 2012, continues to be used in applied GWAS studies, and in methods studies as a standard to compare new methods to

Public high-performance computing resources

- Open Science Grid (NSF) –
 - Distributed network of clusters at many institutions share jobs
 - Explicitly mentions permutation tests as an example of ideal use
(<https://support.opensciencegrid.org/support/solutions/articles/5000632058-is-the-open-science-grid-for-you->)
- XSEDE (NSF)
 - Provides access to NSF-owned clusters
 - Competitive proposal approval process with limited resources at first
- SUMMIT (DoE)
 - Most powerful cluster in world with 4,608 nodes featuring high-end CPUs and GPUs
- NSF National Center for Atmospheric Research Computational & Information Systems Lab

Published parallel implementations of FaST-LMM not appropriate

- "Embarrassingly parallel": Can be parallelized simply by dividing data, work among computers
 - The case for GWAS with large numbers of phenotypes
 - Relatively easy with common parallel computing frameworks
- Otherwise, implementations intended for single massive GWAS
 - 2018 implementation by FaST-LMM inventors
 - 2019 Master's thesis

Ludicrous Speed Linear Mixed Models for Genome-Wide Association Studies

A MODULAR PARALLEL PIPELINE ARCHITECTURE FOR GWAS APPLICATIONS IN A CLUSTER ENVIRONMENT

A Thesis Submitted to the
College of Graduate and Postdoctoral Studies
in Partial Fulfillment of the Requirements
for the degree of Master of Science
in the Department of Computer Science
University of Saskatchewan
Saskatoon

By
Faheem Abrar

Multi-trait analysis can increase power when correlations exist between traits

– increasingly common in poplar community

- Approach 1: GWAS with multiple response variables (phenotypes)
 - Options built into GEMMA, GMMAT
 - Add-ons for SKAT and FaST-LMM (e.g. Multi-SKAT)
- Approach 2: Network-based methods to analyze relationships between large numbers of phenotypes influenced by many of the same QTLs

Multitrait genome-wide association analysis of *Populus trichocarpa* identifies key polymorphisms controlling morphological and physiological traits

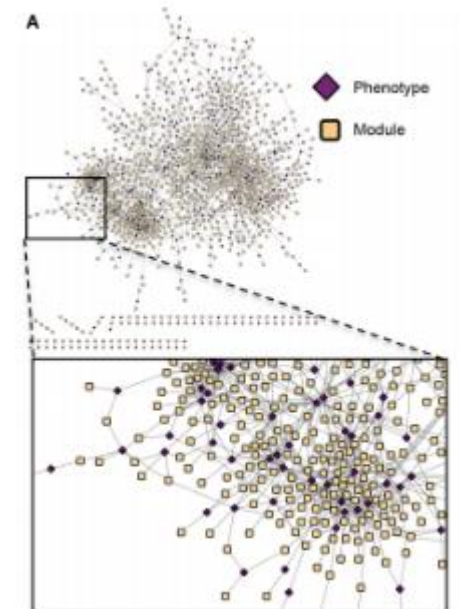

Hari B. Chhetri¹, David Macaya-Sanz¹, David Kainer², Ajaya K. Biswal^{3,4}, Luke M. Evans¹, Jin-Gui Chen², Cassandra Collins⁵, Kimberly Hunt⁵, Sushree S. Mohanty³, Todd Rosenstiel⁶, David Ryno⁴, Kim Winkler⁵, Xiaohan Yang², Daniel Jacobson², Debra Mohnen^{3,4}, Wellington Muchero², Steven H. Strauss⁷, Timothy J. Tschaplinski², Gerald A. Tuskan² and Stephen P. DiFazio¹

Network between module (cluster of SNPs) and phenotype (MP Network) provides insight into related traits in poplar (Weighill et al. 2019)

B Degree Distribution of Phenotype Nodes in MP Network

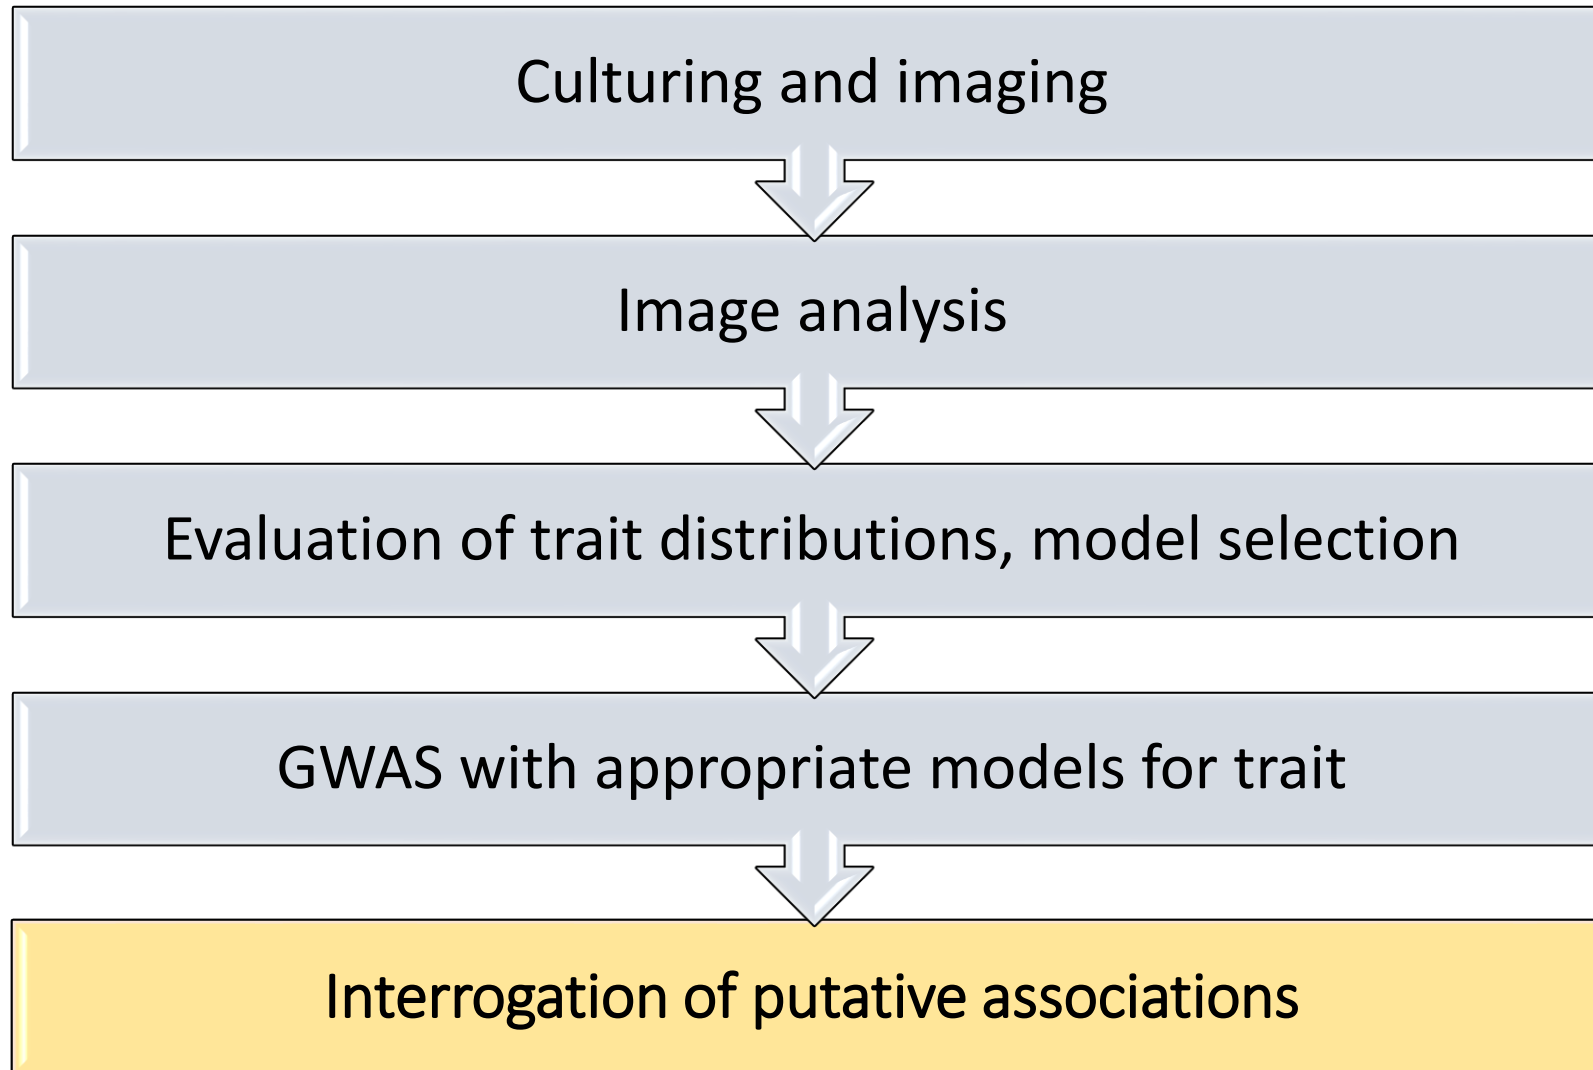

C

<https://doi.org/10.3389/fgene.2019.00417>

From phenotyping to GWAS and beyond

Approaches to interrogating putative SNPs by making use of available knowledge on homologs

A general approach for SNPs in/near genes uncharacterized in poplar

Functional evidence

- **Computational methods:**
 - Epistasis analysis to detect conservation of gene-gene interactions between Arabidopsis and poplar homologs
- **Mutant studies:**
 - If QTL is in/near transcription factor: Transient agroinfiltration with overexpression vectors and qPCR to study downstream genes
 - *In vitro* transformation and regeneration assays with overexpression vectors

Learning about possible homologs

- BLAST or similar alignment tools to find homologs
- Literature review for homologs (basic literature in Arabidopsis, other model/nonmodel plants)
 - Role in cell fate determination?
 - Expression patterns?
 - Role in wider genetic regulatory network?

Transcriptomic evidence

Available poplar transcriptome resources (Phytozome.doe.gov)

- Co-expression data (tissues including leaf, xylem, root from ORNL)
Figure above shown from [Tuskan et al. 2018](#)
- eQTL analysis
- Promoter analysis to identify conserved regulatory motifs

Example of validation by epistasis: Effect of PtT5L1 on shoot depends on LHW homolog

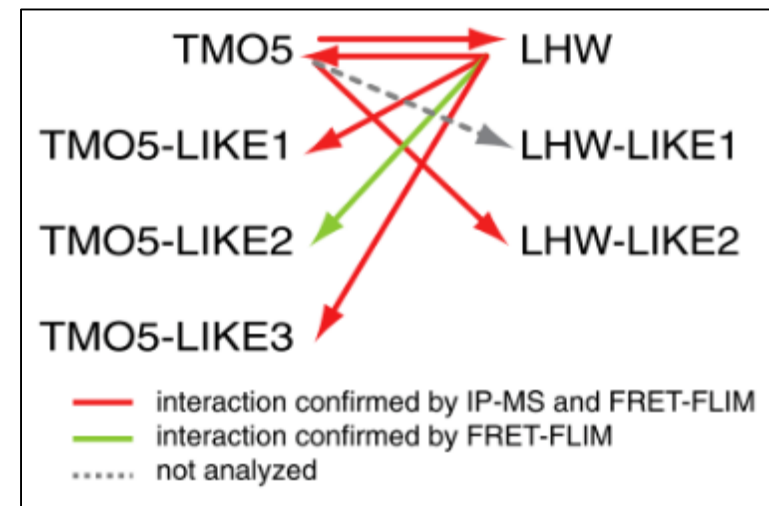

- Limited SNP set including 96 poplar genes (with 1044 SNPs) that are related to Arabidopsis TMO5 or LHW (Smith-Waterman score >200)
- Ran logistic regression on binarized shoot phenotype to avoid violating normality assumption
- Interaction between SNPs in PtT5L1 and PtLHW-LIKE1 ($p=3.109e-08$)
 - Survives Bonferroni correction (threshold of $5.6e-06$)

LR tests for interaction terms
between TMO5, LHW subclades

SNP1	SNP2	$\beta_{interaction}$	p_0
Chr01_6791671	Chr10_14508786	-1.001540	3.109e-08
Chr10_14508513	Chr10_14508898	-0.934245	1.898e-07
Chr10_14508898	Chr10_14509560	-0.925768	2.640e-07

Interaction between LHW-LIKE3 homologs and PtT5L1

Epistasis between intragenic SNPs in PtT5L2

Summary of GWAS methodology

- Distribution of phenotype data dictates GWAS tools that can be used for statistically valid tests
- Shoot phenotypes highly non-normal... several options:
 - Transformation
 - Generalized models
 - Resampling
- Validation of associations
 - Insights from literature
 - Interactome (epistasis analysis)
 - Transcriptome (eQTL mapping, co-expression)
 - Potential for mutant studies?

Next steps for GWAS: Analysis and publication

- Implementation of parallel resampling in FaST-LMM
 - Use of high-performance cluster (NSF Open Science Grid, etc)
- Execution of GWAS workflow with final phenotype data for all traits

Phenotypes	Current status	Next steps	Aim to publish
Stem regeneration (callus and shoot)	Completing additional annotations for MV training	Deploy GWAS workflow, interpret results and write paper	Late 2019 / Early 2020
Rooting	Refining MVmodel	Deploy MVmodel and GWAS workflow	Late 2019 / Early 2020
In vitro regeneration (callus and shoot)	Completing phenotyping	Annotation for MVtraining, GWAS workflow deployment	Early 2020
Transformation	Optimizing transformation methods and treatments	Select treatments and begin GWAS (Winter)	Late 2019

Thank you for listening

Advances in integrated analysis of GWAS and eQTN studies in *Populus trichocarpa*

Jin Zhang
Jay Chen
Jerry Tuskan
Wellington Muchero

Overview and outline

- **Recent improvements to the poplar GWAS panel**
- **Integrating GWAS and eQTN to reveal transcriptional regulation that control of complex traits in poplar**

Current status of the poplar GWAS panel

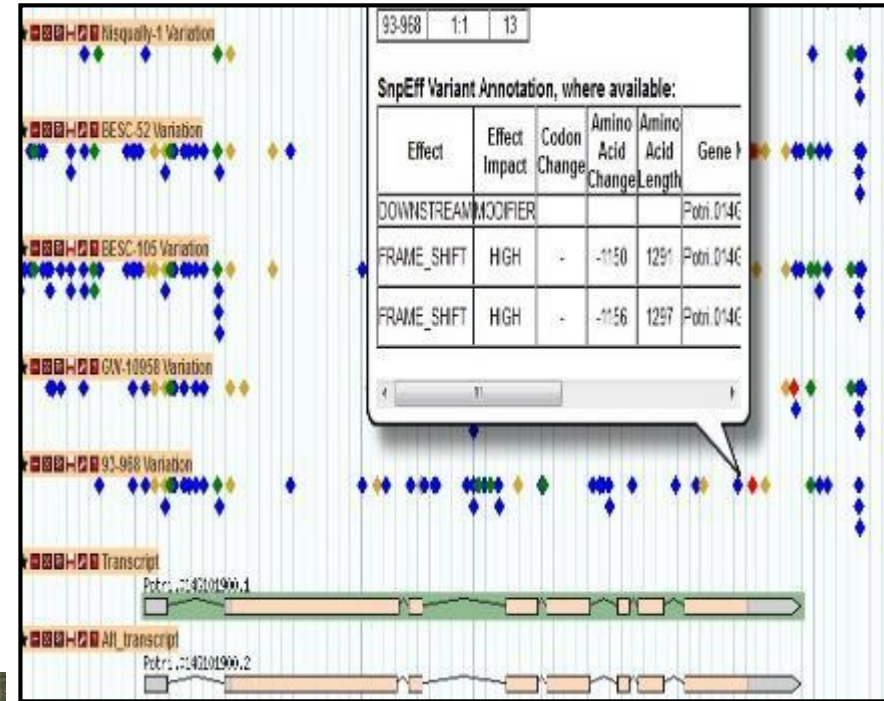

Clatskanie, OR (2009)
Coastal Mesic

Corvallis, OR (2009)
Inland Mesic

Current status of the poplar GWAS panel

Clatskanie, OR (2009)
Coastal Mesic

Corvallis, OR (2009)
Inland Mesic

Boardman, OR (2016)
Inland Xeric

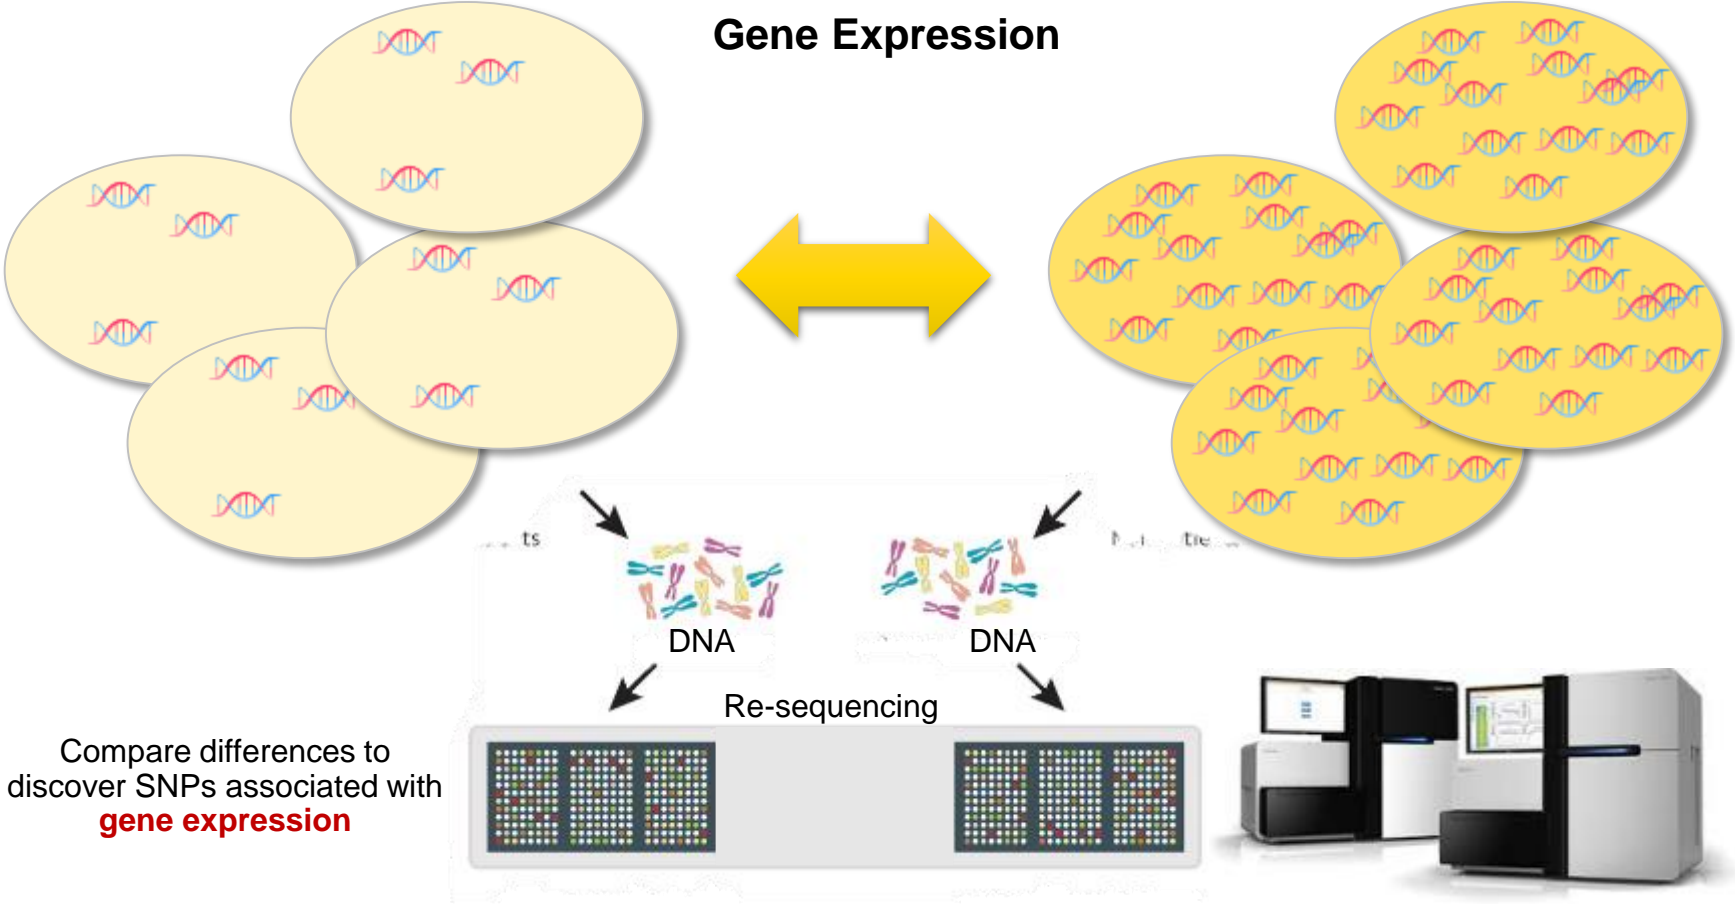

- The selected population / panel
 - 1,352 genotypes
 - Southern BC to Northern CA
 - Established in 3 common gardens
- Genotyping
 - Resequenced at a minimum of 18x depth
 - 29 million high-quality SNPs
 - A SNP every 17 bp
 - LD decays on average within 300 bp and in many cases within <20 bp
- Transcriptome
 - RNAseq data was generated for ca. 500 of the 1250 genotypes for leaves, xylem and roots

$n = 1,352$

Regulation of gene expression by *cis*- and *trans*-eQTN

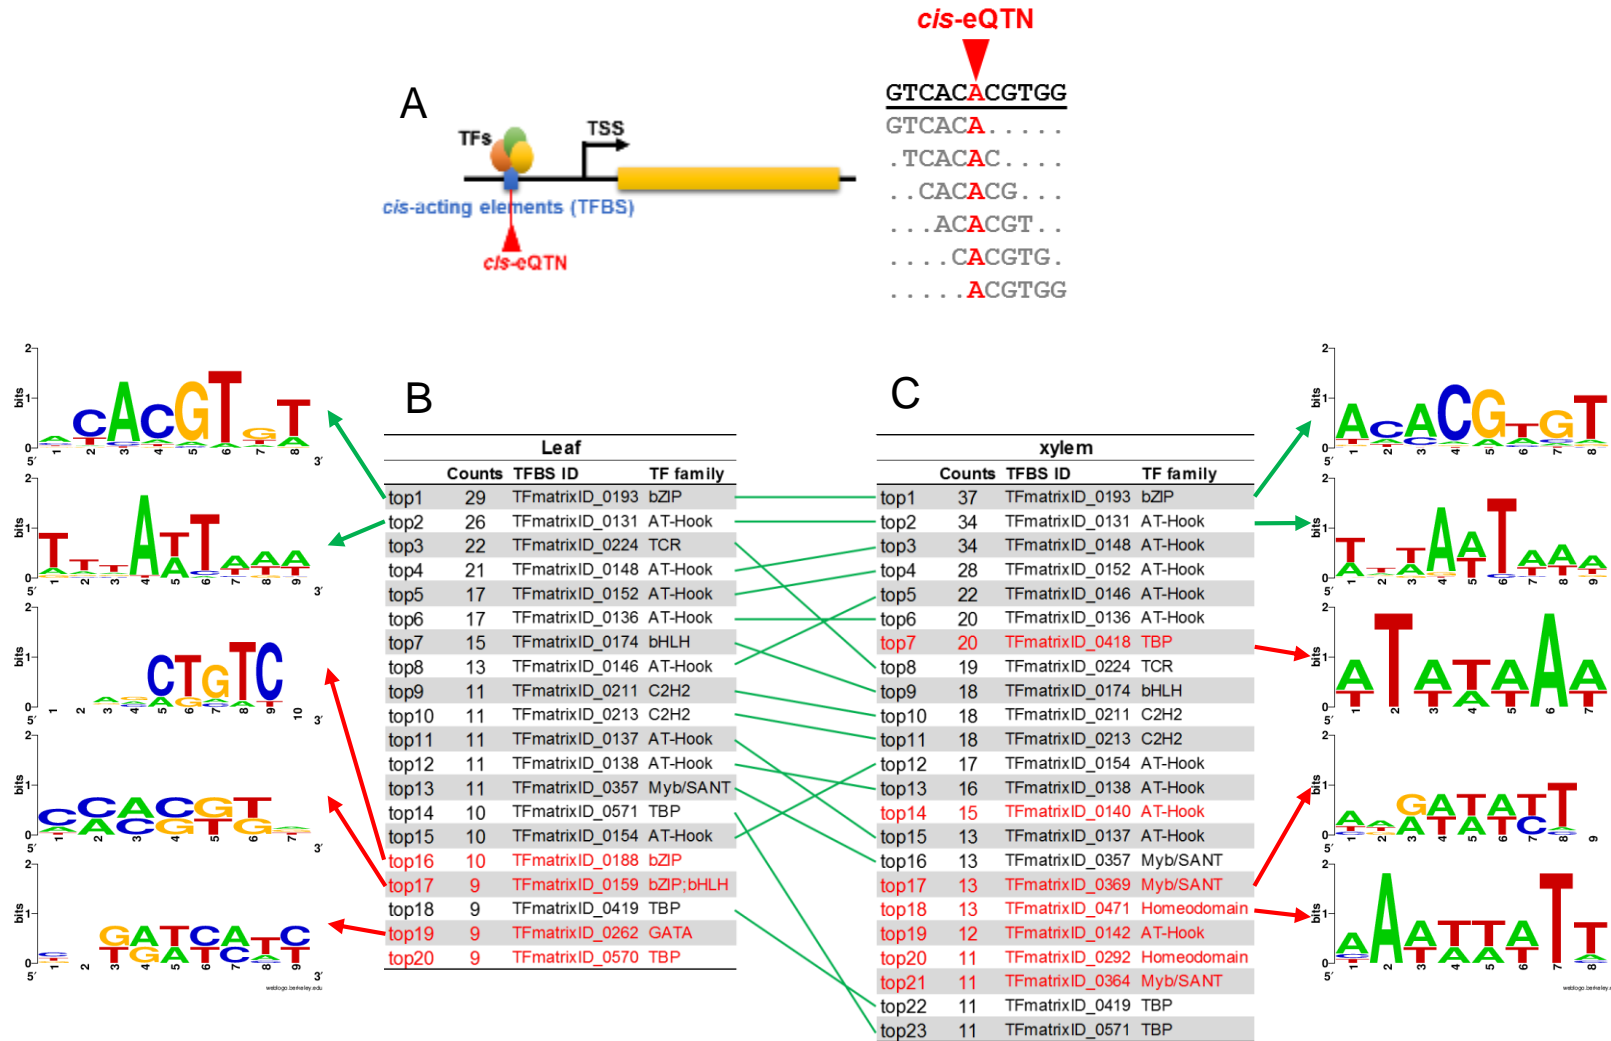

cpn60 chaperonin family protein
T-complex protein 1

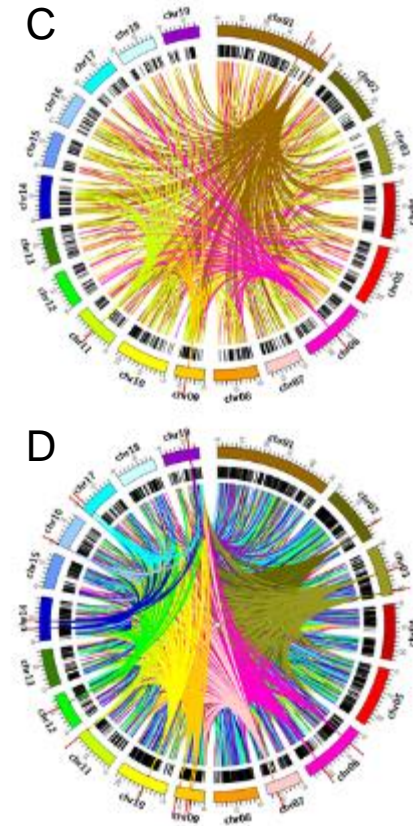

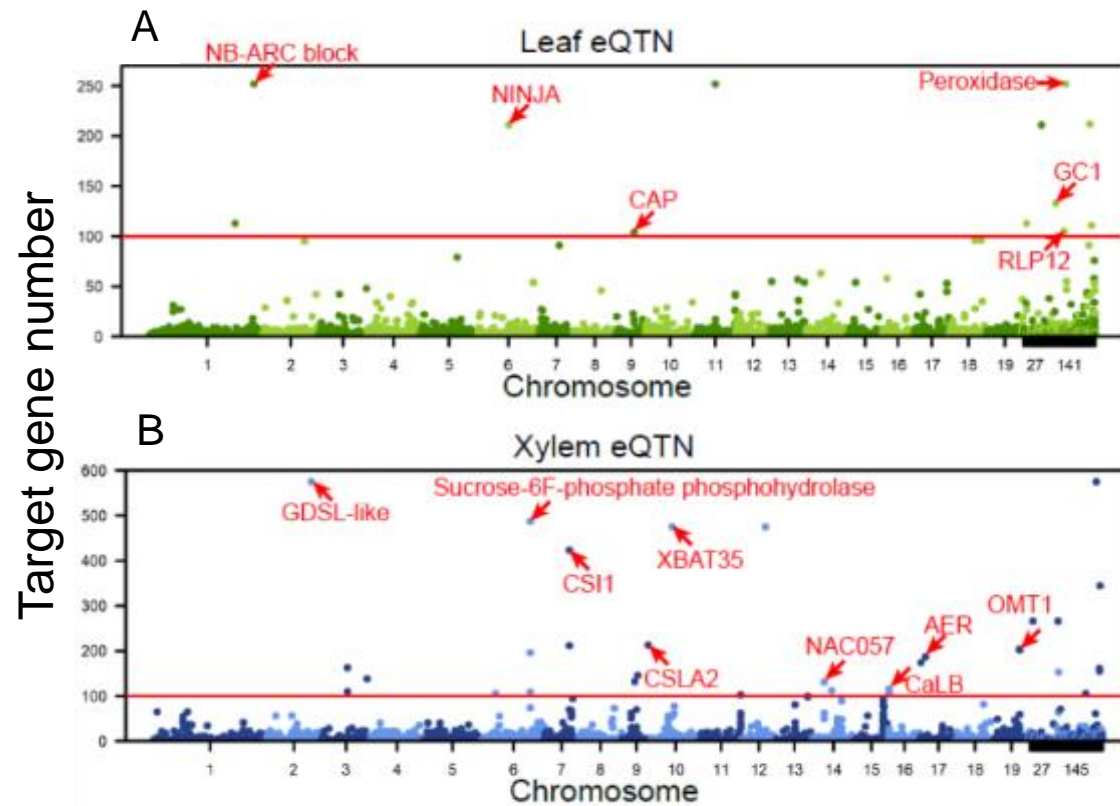

HAC12, histone acetyltransferase of the CBP family 12
Encodes an enzyme with histone acetyltransferase activity that can use both H3 and H4 histones as substrates. No single prior lysine acetylation is sufficient to block HAC12 acetylation of the H3 or H4 peptides, suggesting that HAC12 can acetylate any of several lysines present in the peptides.

Broader Impacts: Education and Curricula

Jay Well, Assistant Director, SMILE Program

Troy Hall, Professor and Department Head, Forest Ecosystems & Society

Betsy Emery, Graduate Research Assistant, Forest Ecosystems & Society

Today's Presentation:

Update on Curriculum Development – Jay Well

- What we've done
- Changes we made from the original proposal
- Next steps--summative assessment
- Milestones and impact
- Dissemination and publication

Update on Social Science – Troy Hall

- Initial data collection process
- Results from initial data collection
- Next steps – testing final curriculum
- Anticipated publications/presentations

Context of the Study:

Education Side

- Overall lack of STEM engagement among students in the US
- Decreasing public scientific literacy + increasing science complexity
- Increasing gaps between scientific and public understandings of science

Social Science Side

- GM/GE is controversial among adults in the U.S.
- Most studies focus on adult attitudes - what about youth?
- Youth are future decision makers/leaders

Overall Goal: Increase open-minded deliberation about socio-scientific issues around GE Ag

Specific Goals Outlined in Proposal:

1. Increase high school teachers' content area knowledge, confidence and access to materials for teaching about genetics in society (emphasis on GMO crops)
2. Increase learners' abilities to think critically and introspectively about agricultural genetic technology
3. Increase students' ability to apply scientific knowledge to address complex socio-scientific problems, especially in agriculture

Photo Credit: DesignSpace

Proposed broader impacts approach...

Partner with SMILE – the Science and Math Investigative Learning Experiences program at Oregon State University

- An after-school science and math club for students in grades 4-12 that focuses on increasing STEM literacy among underrepresented students in rural communities across Oregon

Work with SMILE and the biophysical science team to develop two case studies (2-3, 50-minute lessons each) about genetic modification for high school students

Evaluate and improve curriculum in an iterative process in partnership with SMILE teachers

- Pilot curriculum in SMILE after-school science clubs
- Evaluate curriculum with formative assessment to refine and improve lessons
- Disseminate final lessons broadly through teacher networks

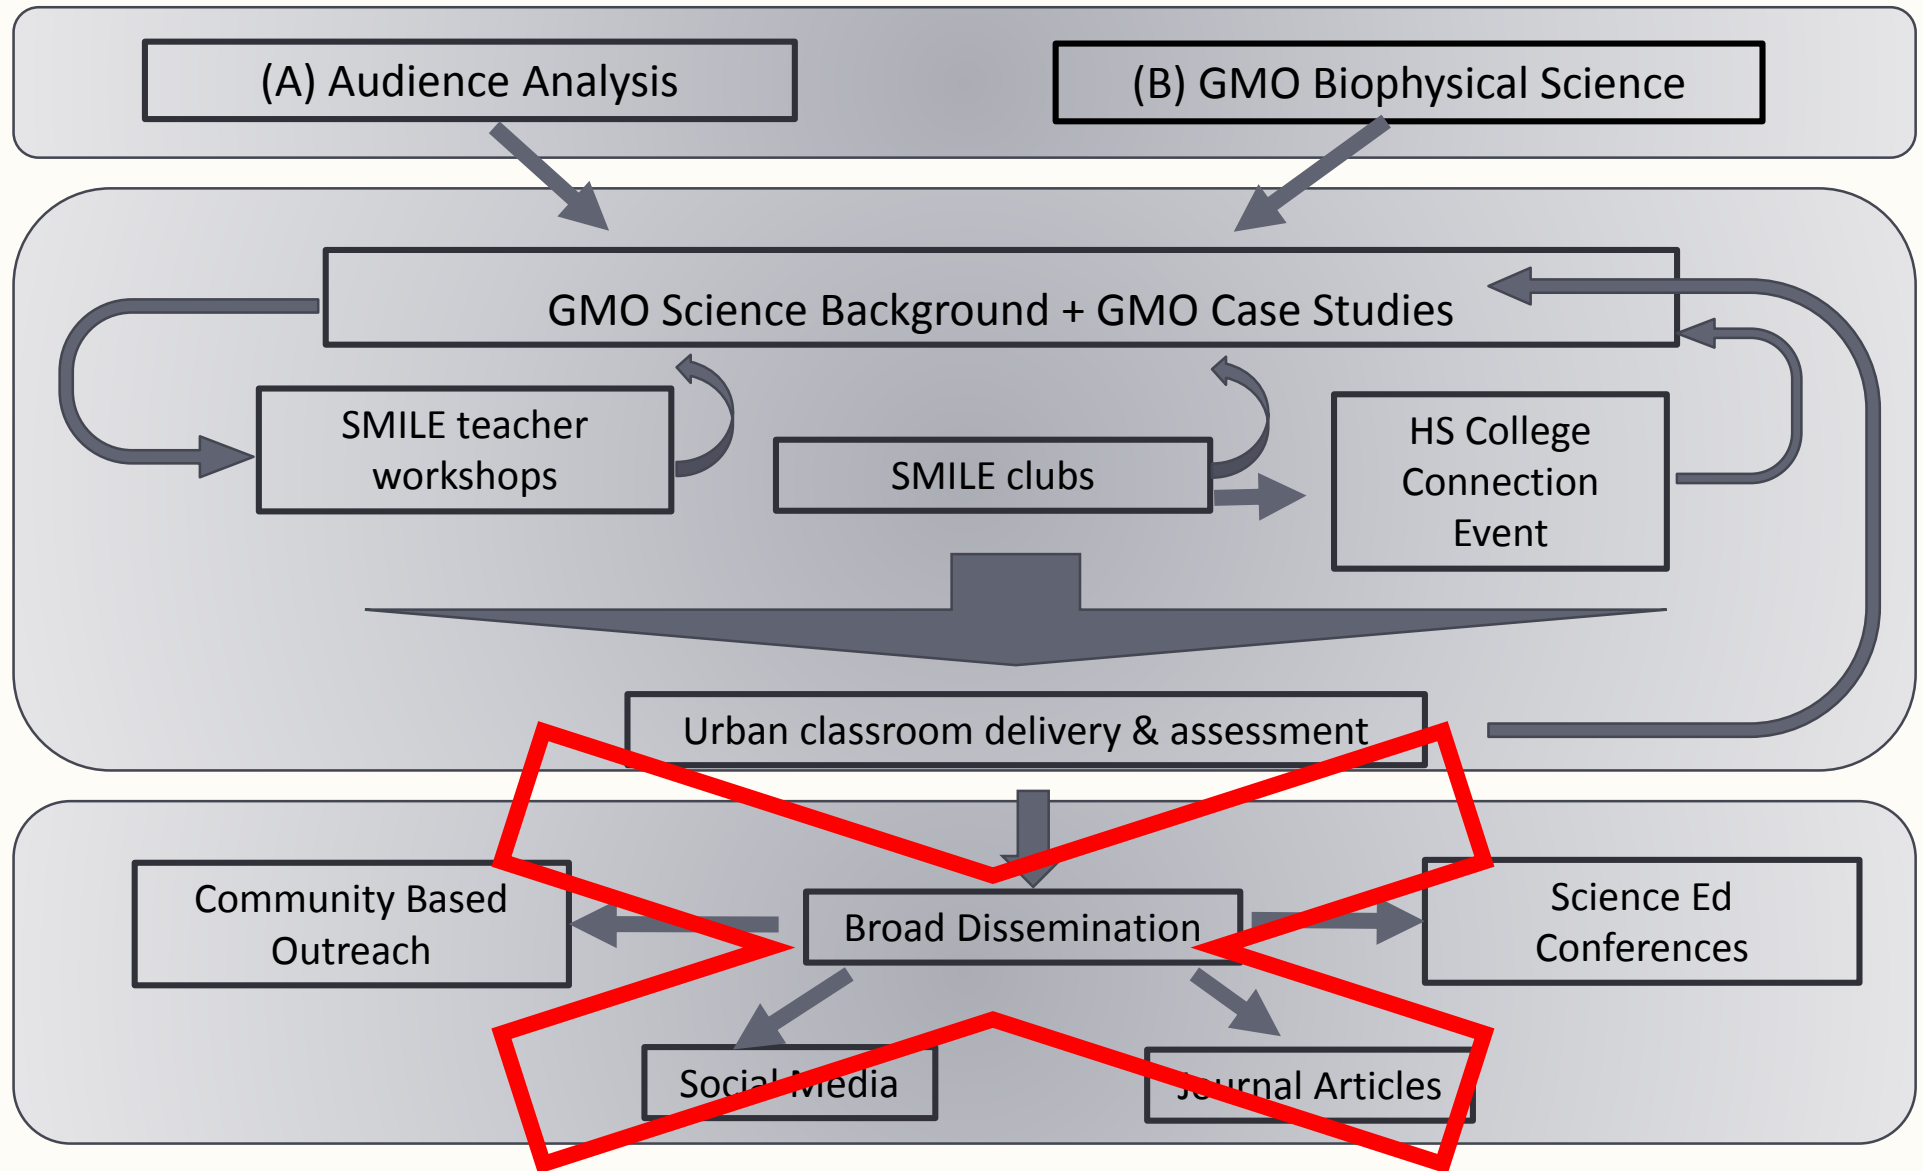

Broader impacts overview

**Initial Assessment:
Audience Assessment
(COMPLETE)**

**Formative Assessment:
Develop, Assess,
Improve, & Evaluate Case
Studies
(NEAR COMPLETION)**

**Summative Assessment:
(IN PROGRESS)**

**Disseminate
(LIMITED IN SCOPE DUE TO
DECREASED NSF FUNDING)**

SMILE serves diverse students in rural communities

707 students (HS 202, MS 322, ES 183)

- 58% female,
- 66% low-income
- 81% first generation to college

Initial Assessment: Audience Assessment (Complete)

Surveyed ~40 SMILE teachers to explore existing cognitions (knowledge, beliefs, emotions, attitudes) regarding genetic modification (April 2018)

- Self-assessed knowledge about GE/genetic modification is low
- Many teachers are neutral or don't know about various GE issues
- Teachers with opinions are overall more positive than negative
- Many teachers felt like they weren't knowledgeable enough to teach GE material

Initial Assessment: Audience Assessment (Complete)

Facilitated **4 focus groups** to understand teachers' comfort presenting GE material, strategies they use and challenges they face in teaching controversial material, and their perceptions of student knowledge/attitudes toward GE/GMOs

- Teachers are comfortable using socially controversial material in their classes
- Students have vague understandings of GE/GMOs and do not tend to have strong attitudes about GE/GMOs
- Teachers face a variety of challenges in teaching GE material
 - Lack of detailed knowledge about the topic
 - Low scientific literacy among students requires teachers to provide lots of background to the topic
 - Difficulty finding materials at the appropriate level for their students

Initial Assessment: Content Selection (Complete)

- Reviewed literature about effective techniques to increase student engagement and ability to think critically; incorporated those into case study design
- Reviewed existing case studies and curriculum to understand gaps and how our curriculum can address these gaps
- Coordinated with GMO biophysical science experts on content and activities included in case studies to ensure they are factually correct

Formative Assessment: Content Development (Near completion)

Audience assessment → switch from a case study focus to broader curriculum

Developed 3 introductory lessons (digital and scientific literacy focus) and 5 lessons about GE

Piloted lessons in SMILE afterschool clubs

Used teacher feedback to improve case studies, which will be used in summative assessment

NOTE: The eight one-hour lessons we developed for this grant are available on the “Broader Impacts” page at: <http://people.forestry.oregonstate.edu/steve-strauss/genes-affecting-plant-regeneration-and-transformation-poplar>

Summative Assessment (In Progress)

Partnering with OSU grad programs: M.S. in Education (Math or Science) and M.S. Agricultural Education

- Curriculum will primarily be implemented by student teachers instead of project staff.
- Project staff will train student teachers on lessons, data collection protocol
- Increases sample size, control over delivery, and efficiency of the project

Will introduce curriculum in high school science classes as part of student teacher placements

- Schools in Portland and other OR communities outside of Corvallis
- Max enrollment: 1,200 high school students (10 student teachers x 4-6 classes x 30 students per class)

Outline of Summative Assessment

Pre-Survey
(knowledge
and attitudes)

120 minutes of
classroom
instruction

Post-Survey
(knowledge
and attitudes)

**Concept map
of GE ag**

**Lesson 1: Eras of
Crop Improvement**
– Overview of plant
modification in ag

**Lesson 2: Fact
Checking in the Digital
Age** – Overview with
specific GE ag
examples

**Lesson 3: Why
Genetically
Modify** – Three
case studies of GE
ag

**Revisit initial
GE ag
concept map**

Changes in Education Project From Proposal

- Shifted from developing case studies about specific GE products to developing multiple lessons geared towards better understanding the science and perspectives
- Only provided a pre-test during data collection in SMILE clubs due to challenges in club timing and controlling for delivery, attendance
 - Will be using pre/post surveys for data collection during summative assessment
- Working with student teachers to conduct summative assessment in addition to project staff to increase efficacy and efficiency of outcomes
 - Will be training student teachers in advance during Fall/Winter
 - Will allow for increased sample size and greater demographic/geographic footprint of the project

Milestones

Curriculum Development:

1. Fact Checking in the Digital Age
2. Methods of Food Modification
3. GMOs and the Nature of Science
4. Eras of Crop Improvement
5. Investigating the GMO Controversy
6. Why Genetically Modify?
7. A Better Banana
8. GE Labeling and Identification

Teacher Professional Development:

August 2018

January 2019

August 2019

January 2020

High School/Middle School Challenges:

- April 2019
- Modifying associated lessons into a 5-day applied genetics MS/HS curriculum

Summative Assessment:

- School Year 2019/2020: Recruiting schools, teachers, delivery winter/spring

Impact by the numbers (through Aug 2019):

- **Total SMILE Teachers: 125 for 546 contact hours (Workshops and Challenges)**
 - Teacher workshops: 88 SMILE Teachers for 264 contact hours
 - MS teachers at challenges: 22 for 132 contact hours (challenge is 6 hours)
 - HS teachers at challenge: 15 teachers for 150 contact hours (challenge is 10 hours)
- **Total SMILE Students (Challenges): 200 for 1504 contact hours**
 - MS students at challenges: 124 for 744 contact hours (challenge is 6 hours)
 - HS students at challenge: 76 students for 760 contact hours (challenge is 10 hours)
- **Total SMILE Students (Clubs): 420 for 840 contact hours**
 - Assuming each student participated in 2 of 6 lessons

Lessons piloted in multiple SMILE clubs

Lesson	MS Clubs	HS Clubs	Total Clubs	Estimated Students Reached (12 students/club)
Fact Checking in an Era of Fake News	5	7	12	144
Nature of Science	4	3	7	84
Methods of Food Modification	7	5	12	144
Eras of Plant Improvement	3	7	10	120
Why Genetically Modify?	6	6	12	144
Investigating the GMO Controversy	3	6	9	108

Dissemination and publication

- Feedback from multiple sources will be used to refine lessons and put in finalized form
- Look to publish lessons in teacher practitioner journal such as National Science Teacher Associations' *Science Scope* or *Science Teacher*
- Presented the first lesson ("Fact Checking...") at the Oregon Science Teachers Association annual conference in October 2018 (31 K-12 teachers participated)
- Further disseminate lessons through partner teacher networks and conferences

Broader Impacts: Social Science

Troy Hall, Professor and Department Head, Forest Ecosystems & Society

Betsy Emery, Graduate Research Assistant, Forest Ecosystems & Society

Jay Well, Assistant Director, SMILE Program

Theoretical Framework:

Overall goal:

increase students' cognitive complexity

move students from heuristic-based, simple “decisions” about GMOs to more nuanced attitudes based on balanced consideration of multiple potential positive and negative aspects

Research Questions:

Initial phase: What knowledge, beliefs, and attitudes do science club students in rural Oregon have about genetic engineering (GE) and genetically modified foods (GMF)?

Summative phase: How do carefully designed curricular materials affect Oregon high school students' beliefs, attitudes, and cognitive complexity regarding GMF?

Initial Phase: Data Collection in SMILE clubs (Complete)

- Baseline knowledge and attitudes
 - 9 SMILE clubs (5 MS, 4 HS)
 - 125 middle school (MS) and high school (HS) students
 - 73 surveys
 - 102 concept maps
- Developed and refined data collection methods to characterize student cognitions
 - Data collection instruments (e.g., concept mapping protocol, pre-test/post-test survey) will be revised for summative evaluation

Initial Data Collection Methods

Concept Mapping
(Data Analysis Complete)

Online Survey
(Data Analysis Complete)

Focus Question:

What are your thoughts and feelings about genetically modifying the foods humans eat?

Content areas:

Beliefs/knowledge; attitudes

Variables, Measurement, and Analysis

Variable	Measurement	Analysis
Belief Structure	Concept maps	Scoring of map structure & content (topics, elaboration)
Knowledge	6 survey statements: self-assessed knowledge about GE and GMF	Knowledge Index Score
Beliefs	7 survey statements: (dis)agreement with claims about GE and GMF; concept map nodes	Descriptive statistics
Attitudes	3 survey statements: attitudes toward GE applications; concept map valence	Attitude Index (mean level of support); Frequencies (concept maps)

Concept Maps:

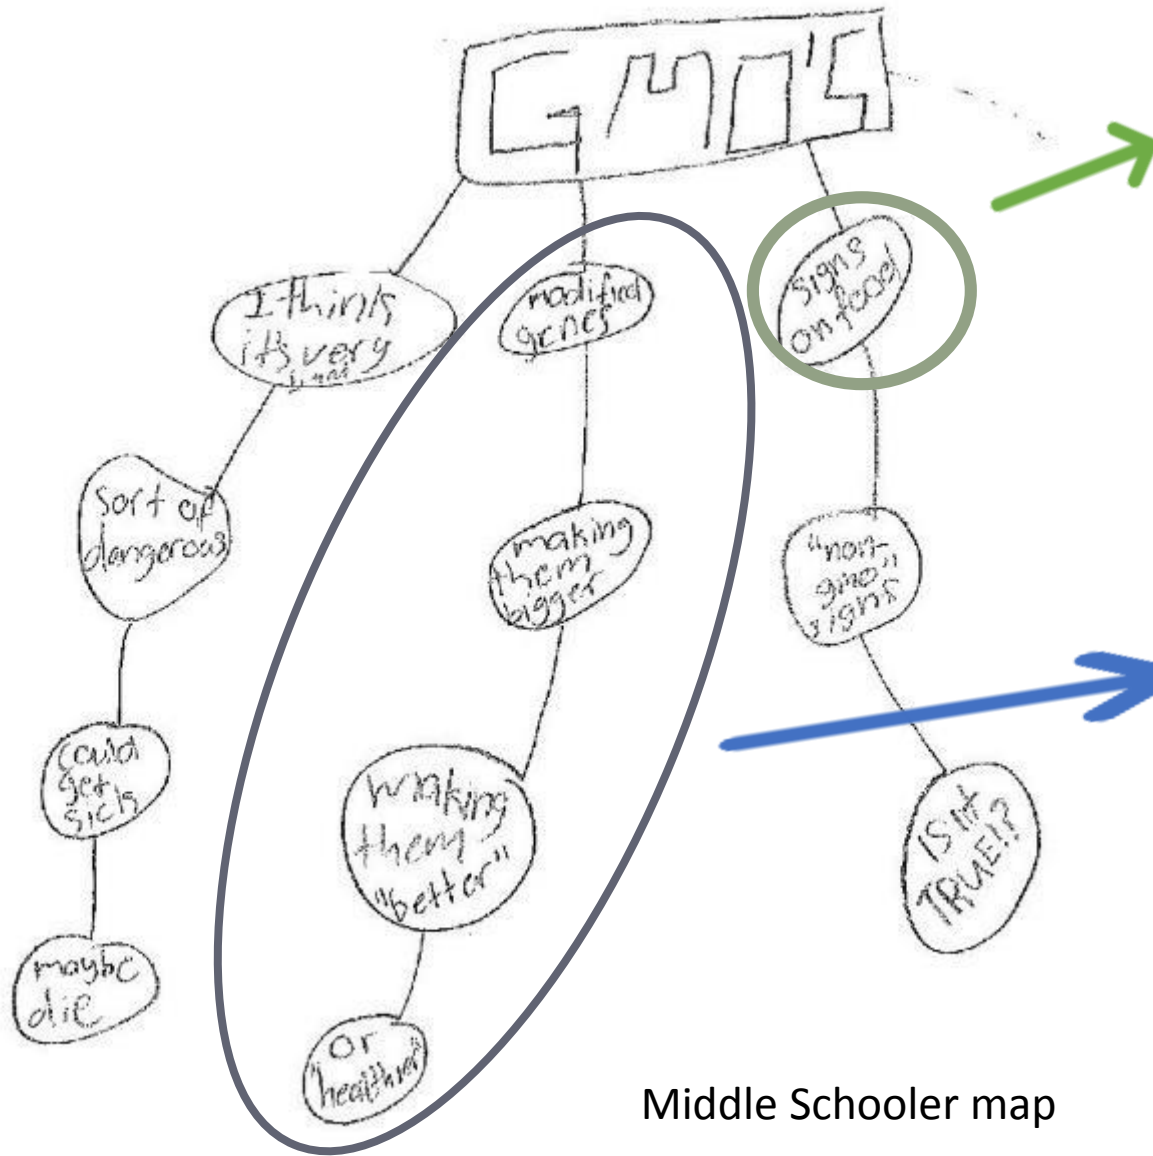

Procedure:

- 15 minutes training on a different topic (social media)
- Instructions seeded 20 concepts in a word bank (e.g., “benefits,” “costs,” “environmental impacts,” etc.)

Analysis to answer 3 questions:

- What are students' unprompted beliefs about GMO foods?
- How are those beliefs structured?
- What are the students' attitudes toward GMO foods?

Concept Maps – 3 levels of “coding”

Middle Schooler map

First level: Concept

- **Code**

- 21 separate topic codes
- E.g., costs, science, chemicals, agriculture

- **Valence**

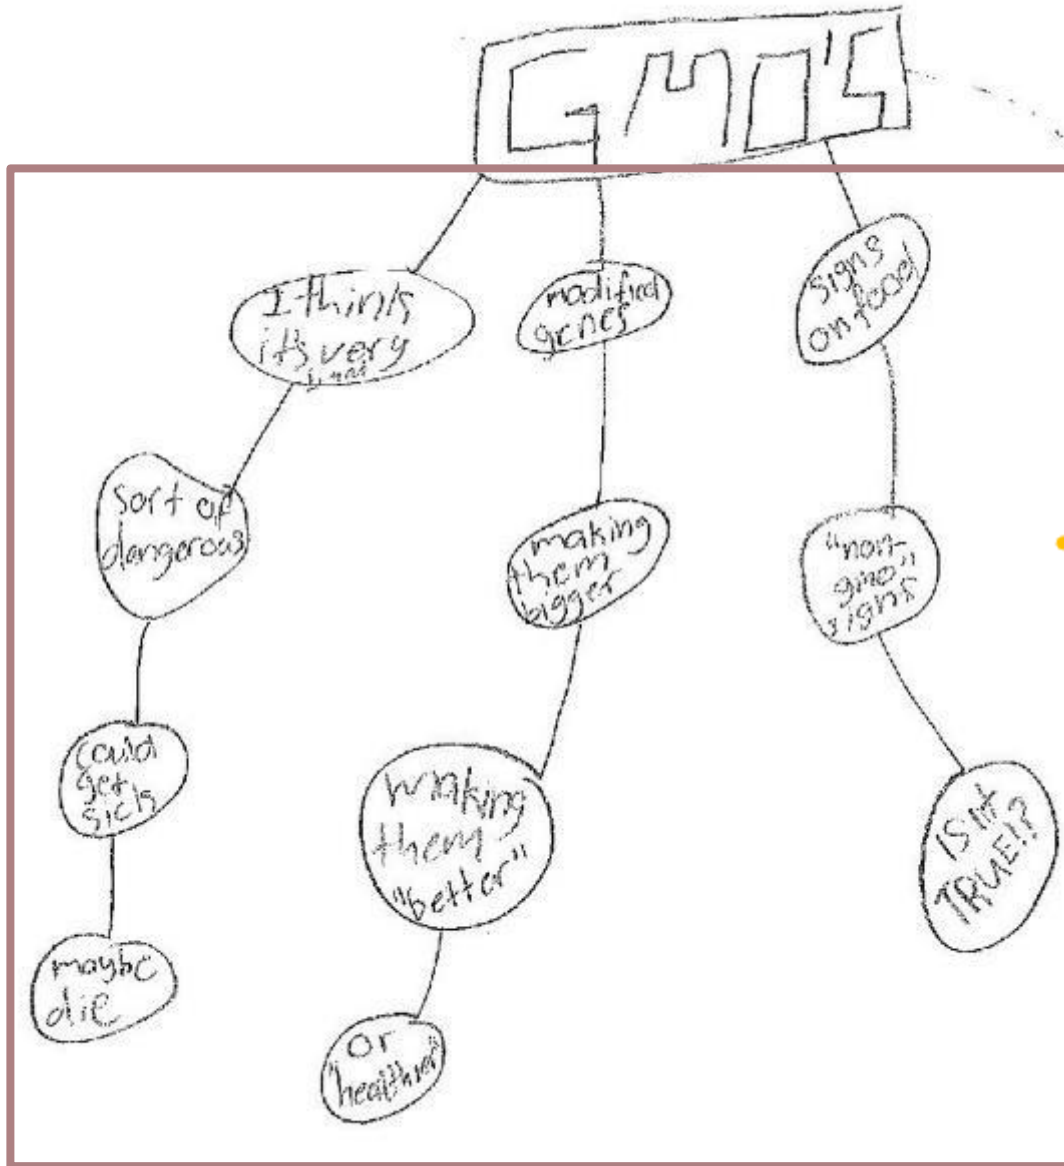

- positive, negative, ambivalent, unknown

Second Level: Cluster

- **Valence**

- **Elaboration** (depth of thinking)

Concept Maps – 3 levels of “coding”

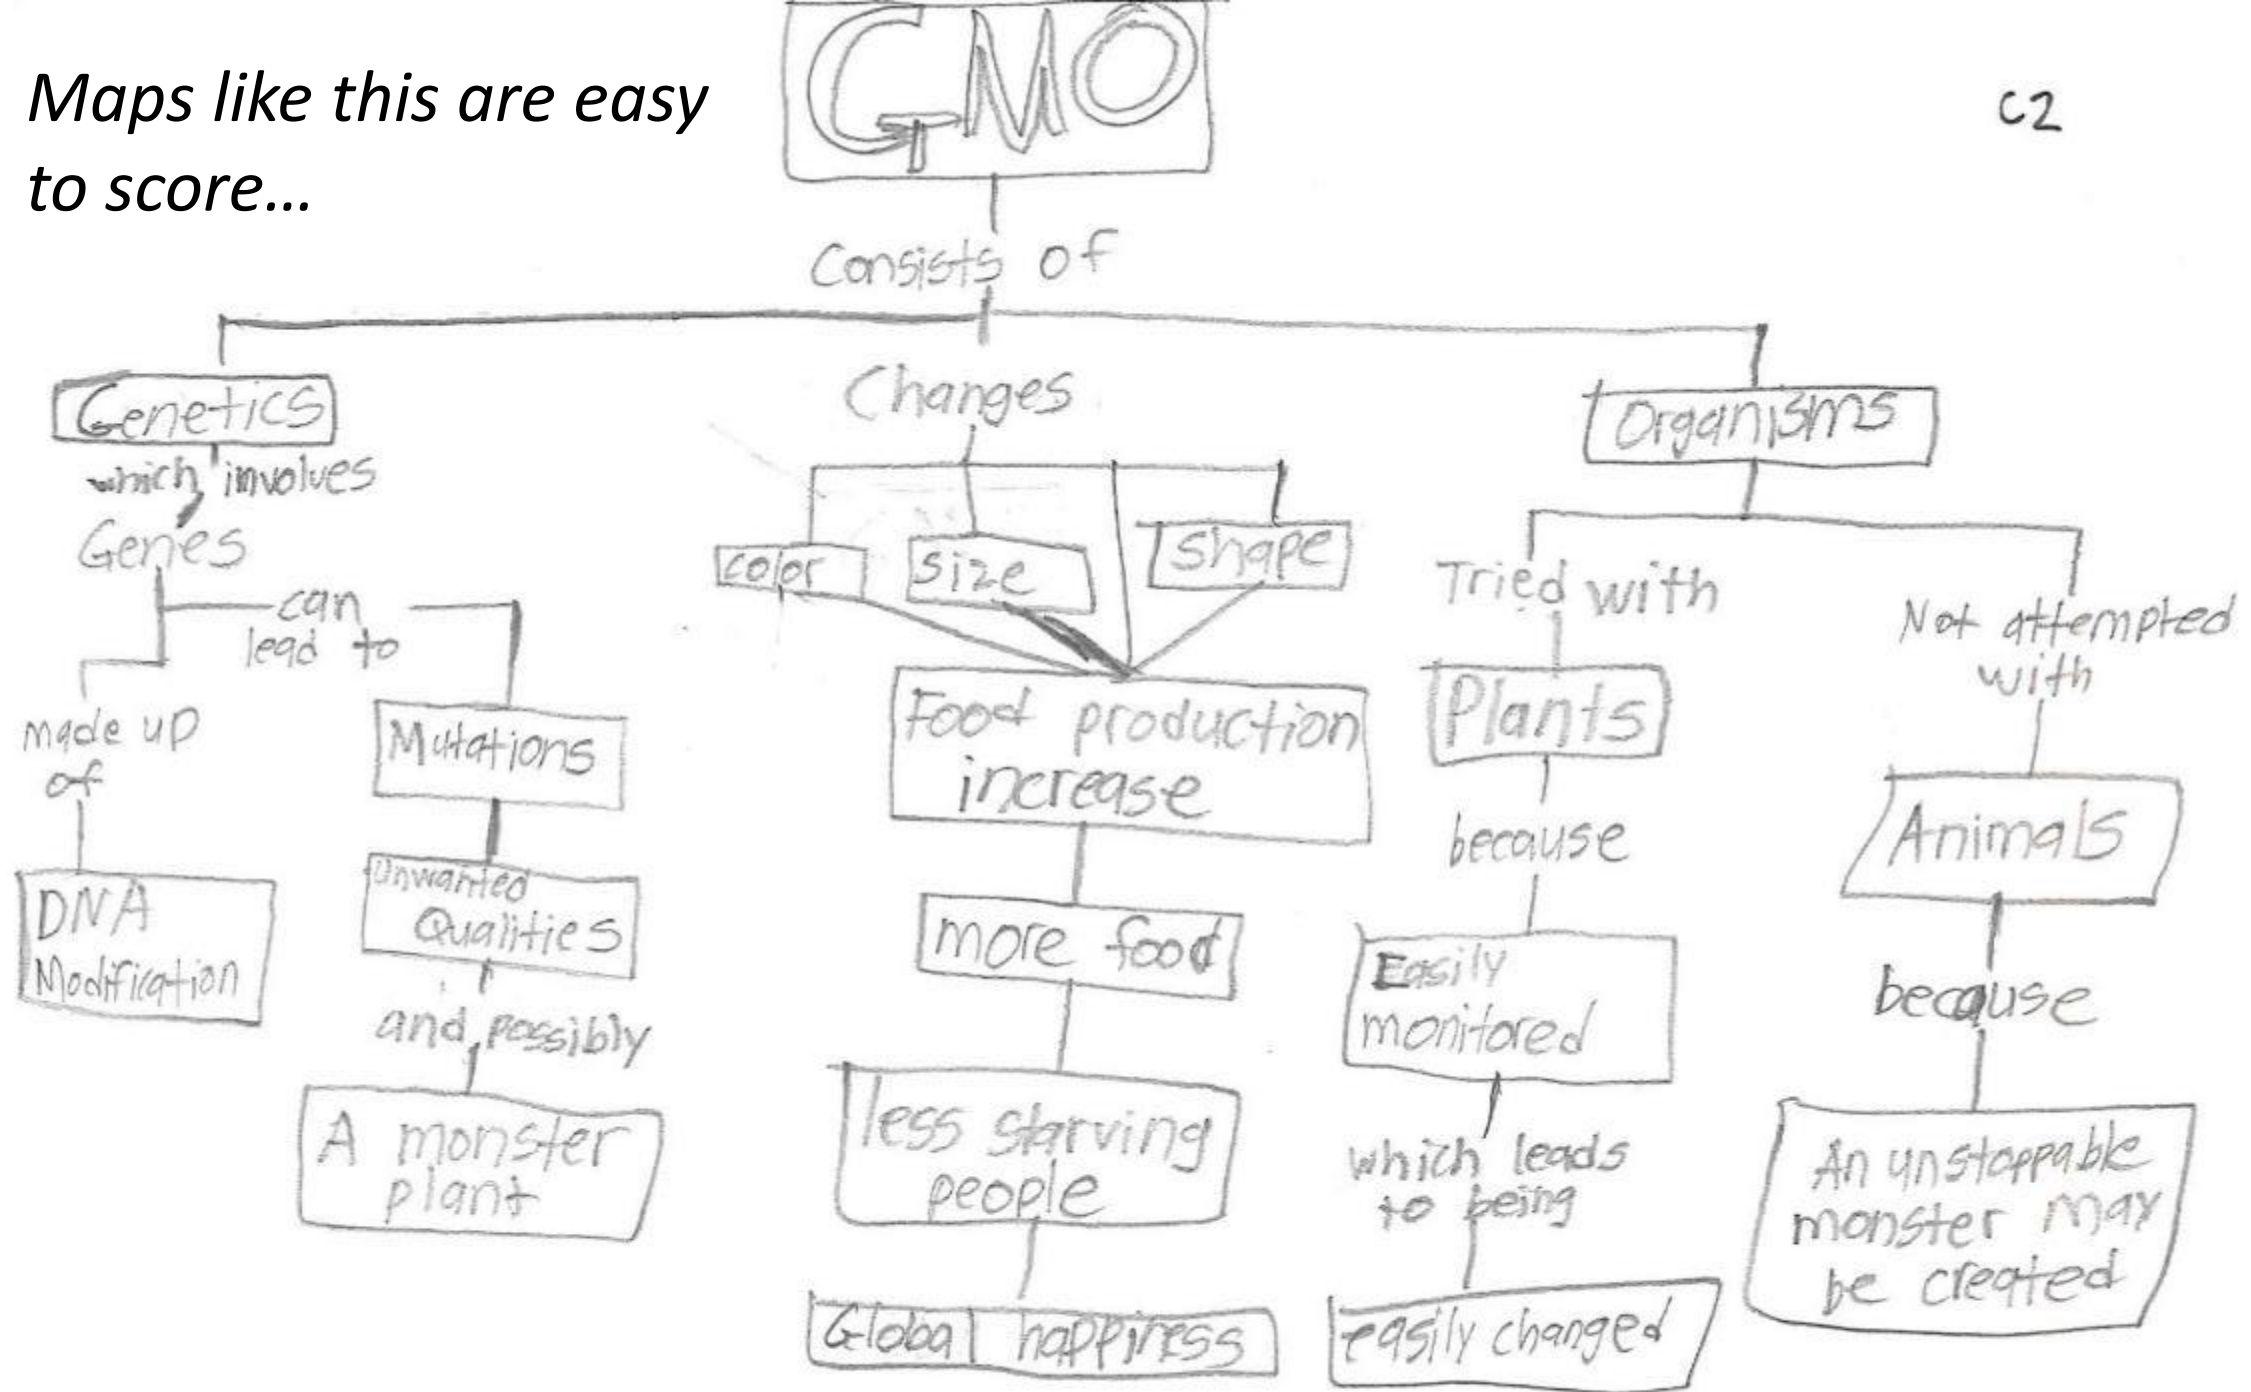

Third Level: Map

- **Map Type (belief structure):**
 - chain, spoke, network
- **Cross-links:**
 - Number of connections between clusters
- **Overall Map Valence:**
 - 0: no apparent valence
 - 1: all positive
 - 2: more positive than negative
 - 3: ambivalent
 - 4: more negative than positive
 - 5: all negative
- **Word Bank Words:**
 - # Words used from the word bank (0-20)

Challenges with Concept Maps

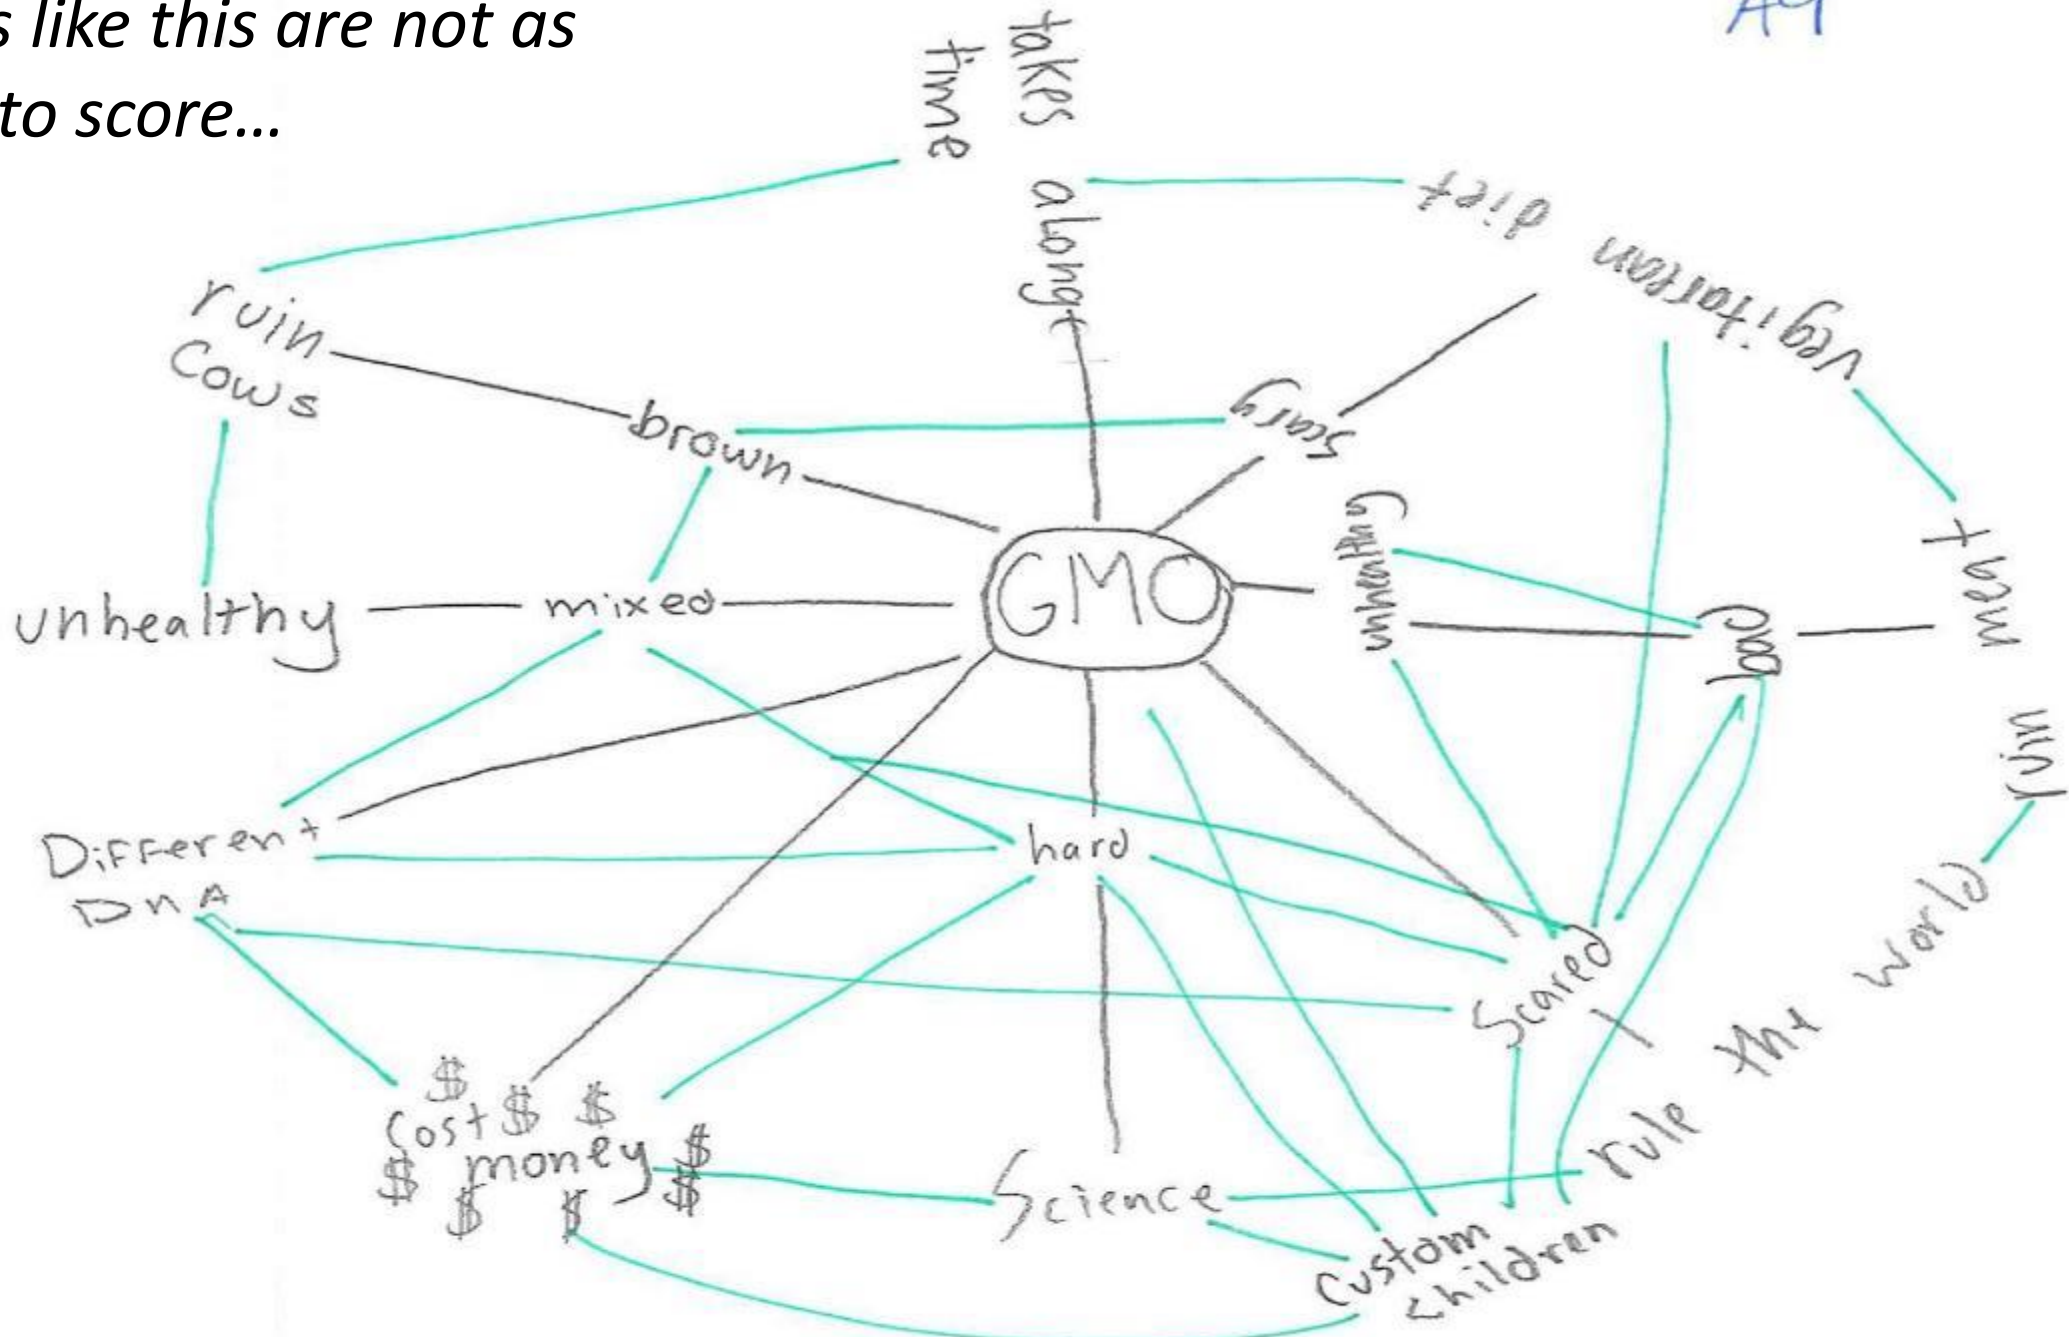

Maps like this are easy to score...

C2

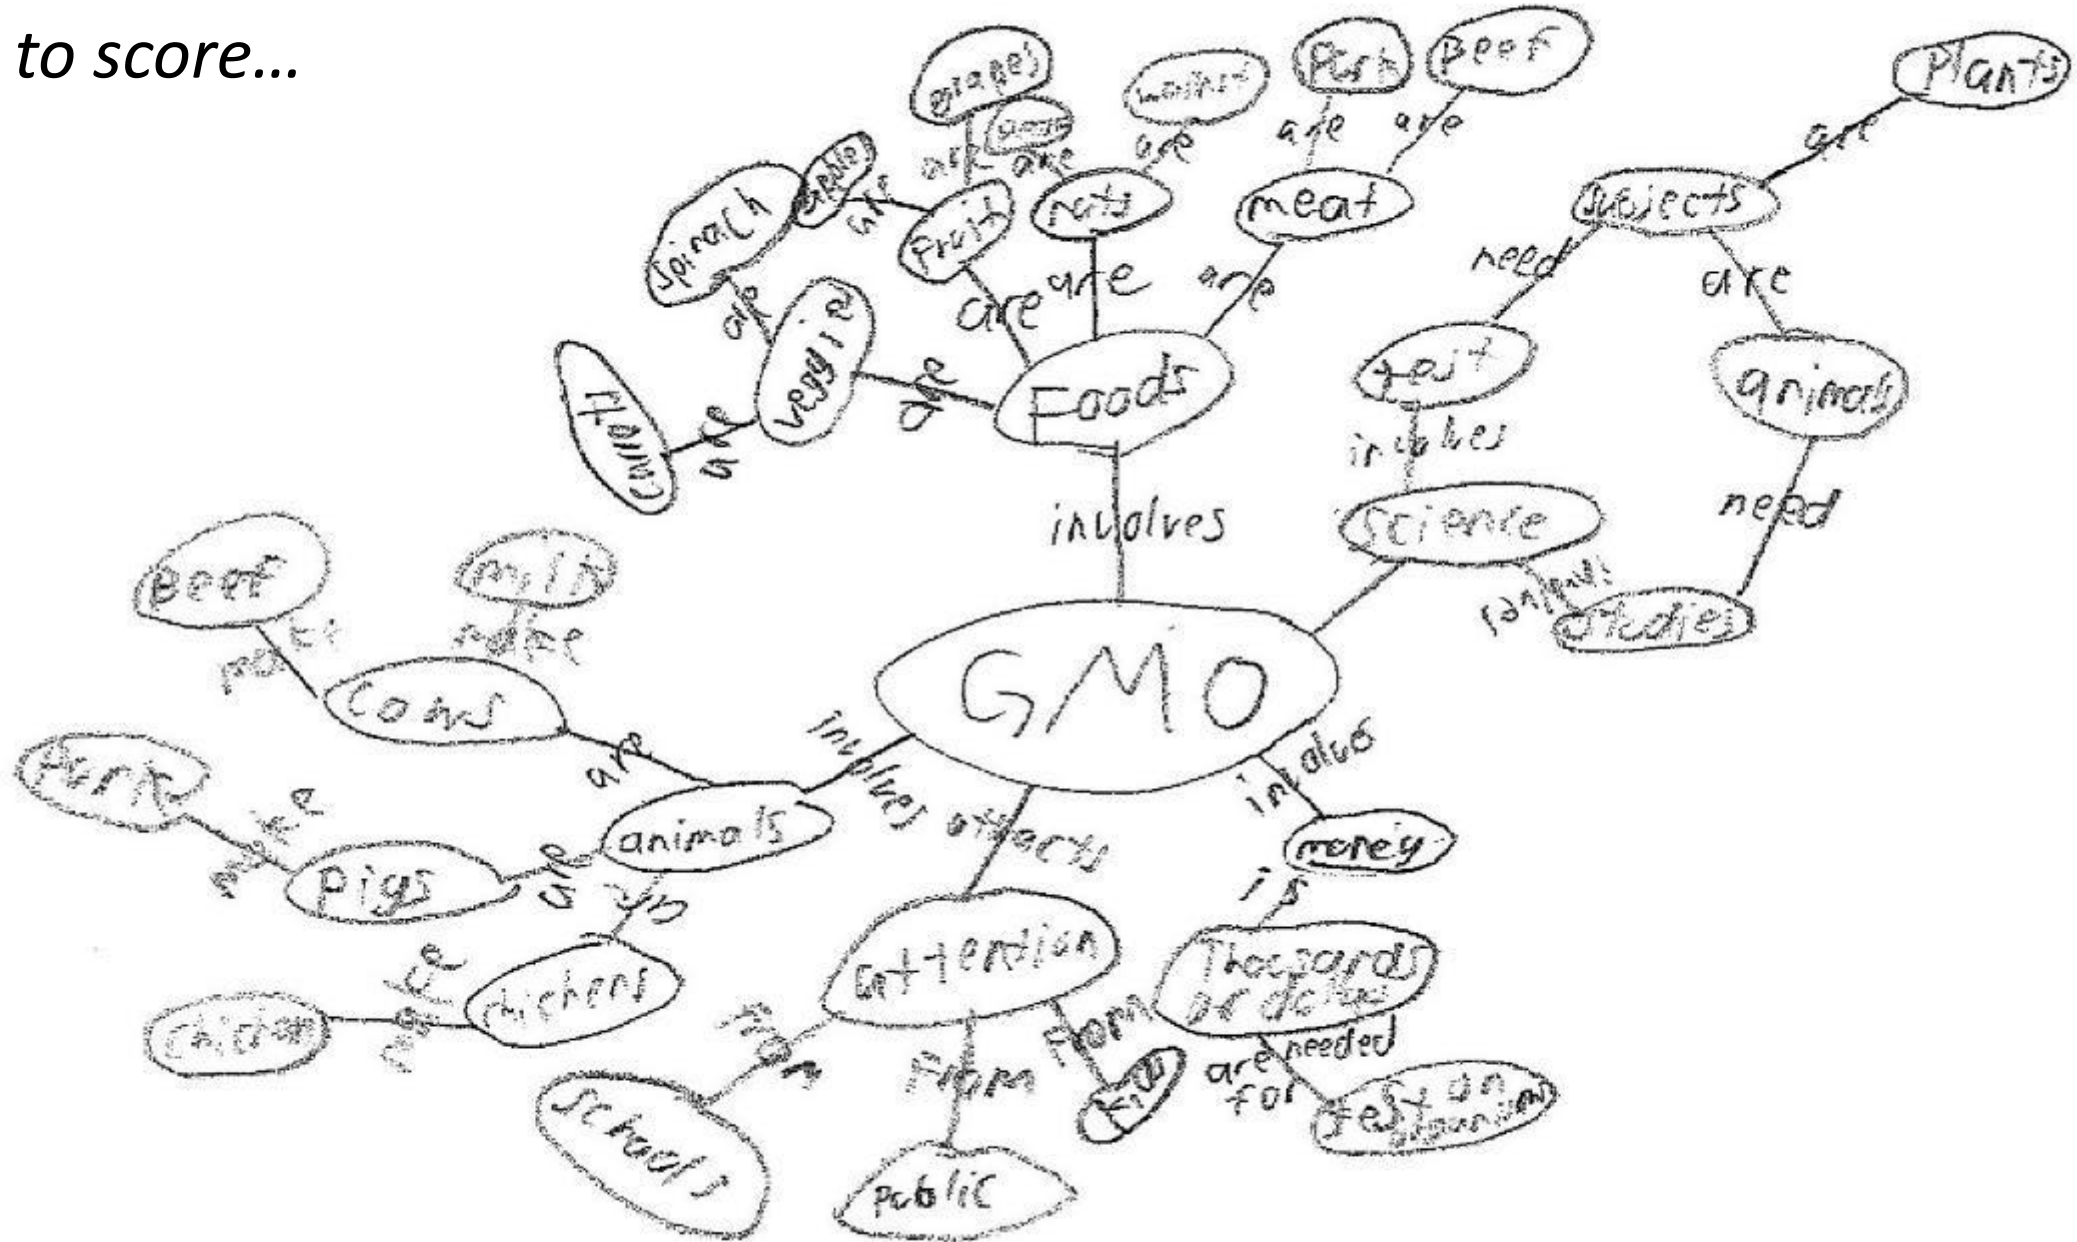

Maps like this are not as easy to score...

A9

Maps like this are not as easy to score...

Concept maps: What are students' beliefs about GMOs?

- Many students created a “base map” → not a topic of interest or familiarity?
- Several concepts were common (% of maps; **red = word bank**):
 - **Food** (~35% positive; ~10% negative)
 - Trait modification (~25% positive; ~5% negative)
 - **Human health** (~25% positive; ~40% negative)
 - “Chemicals” (0% positive; ~15% negative)
 - **Environmental impacts** (~7% positive; ~15% negative)
 - **Cost** (~10% positive; ~20% negative + ~25% “costs a lot”)
 - **Feelings** (~25% of maps; more neg than pos)

Concept maps: How much do students elaborate their thoughts on GMOs?

NOTE:

Elaboration is coded at the cluster level

1

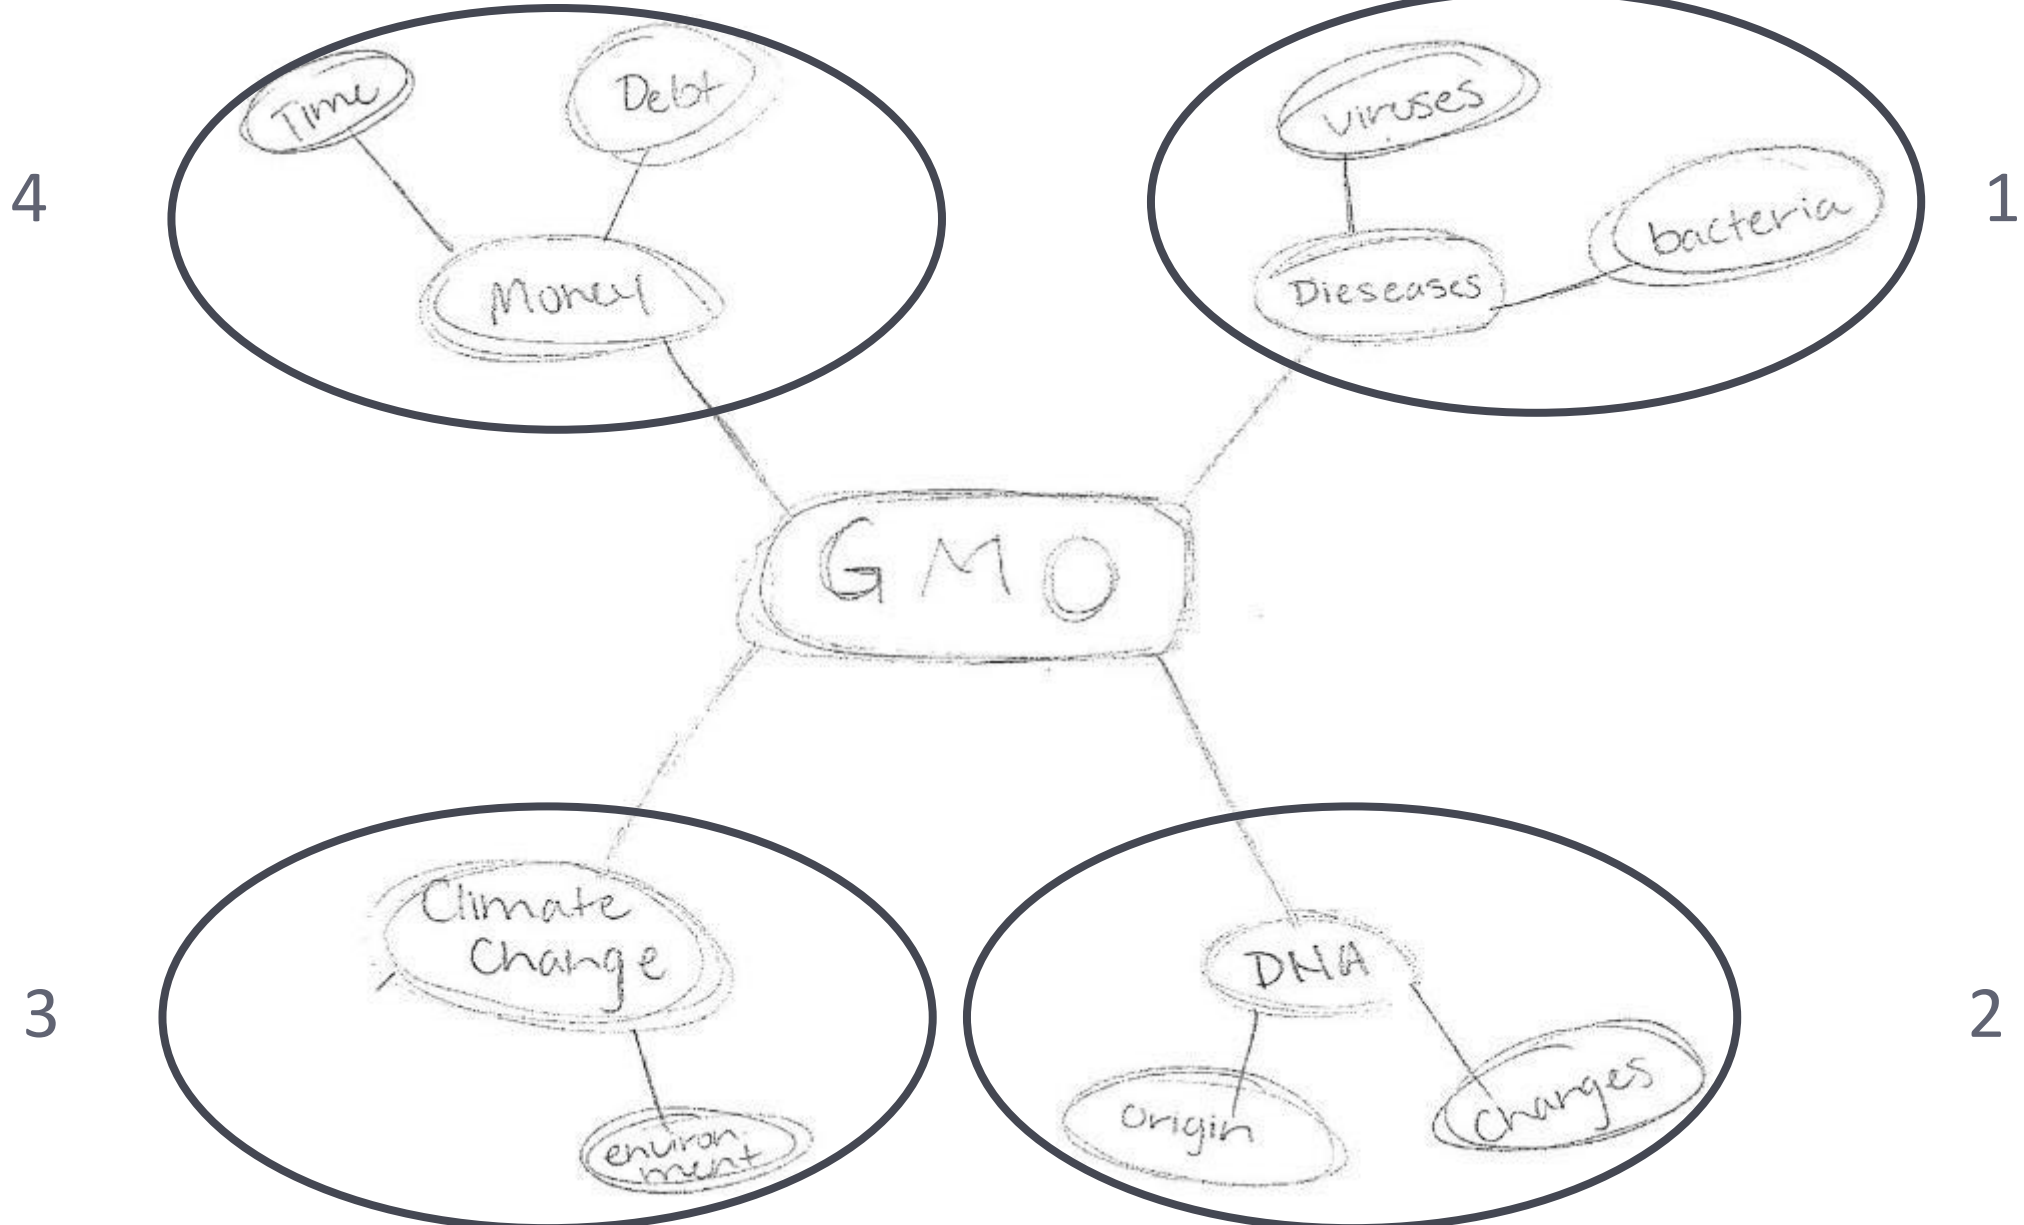

2

3

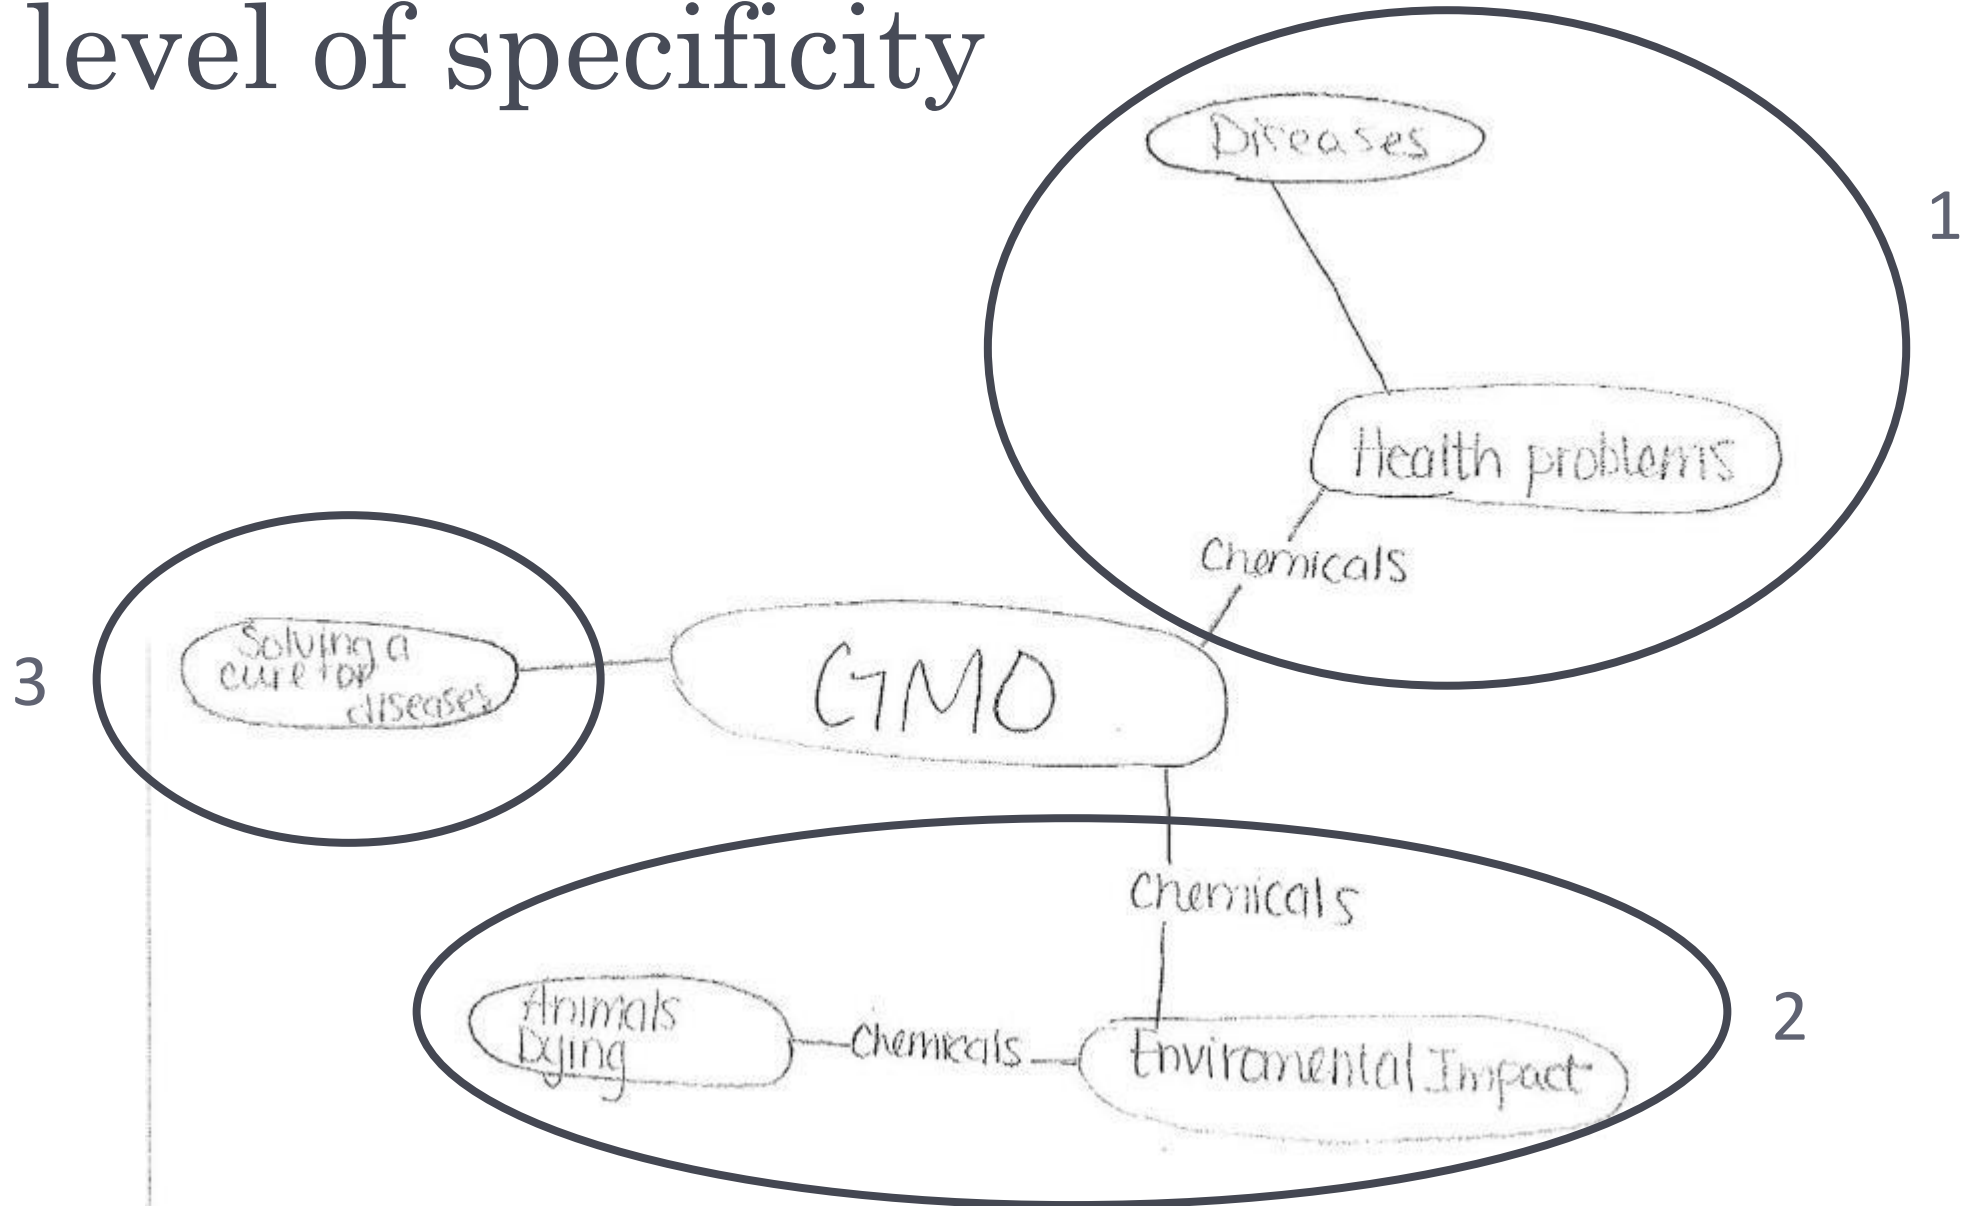

4

5

Differences between low and medium elaboration scores

Medium and high scores really distinguished by level of specificity

Concept maps: elaboration scores

Survey: Knowledge Index

Question	% correct
Some genetically modified plants grow faster than non-genetically modified plants	48
Some plants have been genetically modified to make foods with more minerals and vitamins than traditional crops	44
All food products made from genetically modified plants contain DNA	26
Some plants have been genetically modified to make foods that last longer	16
Traditional crops can become contaminated by pollen from genetically modified plants	16

Low level of knowledge corroborated by data on self-reported knowledge

Survey: Beliefs

Students do not have strong beliefs about GM

Survey: Attitudes toward GM applications

	Mean*	SD	% support
Genetically modifying plants to produce medicines for humans	2.50	1.09	50
Genetically modifying plants to produce food for humans	2.68	0.95	47
Genetically modifying plants to produce food for farm animals	2.56	1.02	50
Index (Mean)	2.58	0.77	

*1=strongly support; 5 = strongly oppose

Concept maps: Overall attitudes about GM foods

Data did not support expectations of primarily negative attitudes

Overall Conclusions from Initial Assessment:

- Students are generally **not very knowledgeable** about GM/GMF
 - Low self-assessed knowledge, low knowledge index scores, and evidence of uncertainty
 - Reliance on seeded words in concept map
 - Other international studies (Taiwan, UK, Netherlands, Australia) also show that students are not very knowledgeable
- Students tend to have **ambivalent attitudes**: they associate both positive and negative outcomes with GM/GMF

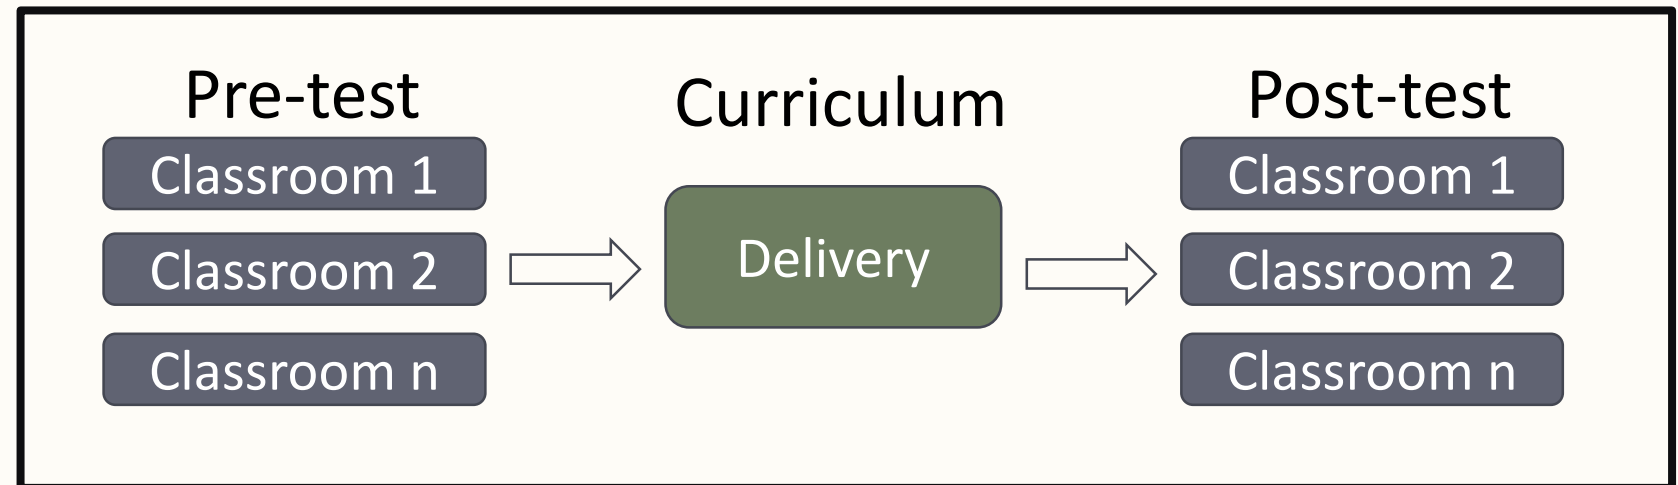

Initial Assessment -- Next Steps:

Manuscript for submission to *Journal of Agricultural Education* for review (Fall 2019)

Summative Evaluation (In Progress)

- Use curriculum described previously
- Quasi-experimental design
 - Pre-tests/post-tests (survey & CM) with high school students
 - Interviews with student teachers re: experience using lessons in class

Summative Evaluation (In Progress)

- Data collection: Fall 2019 – Winter 2020
- Advantages to study design
 - Trained instructors – reduces variation in delivery
 - Wide range of classes – large sample
 - Simulates reality of material delivery in classes (time constraints)

Summative Evaluation (In Progress)

- Status
 - Refining questionnaire items to reflect curriculum content
 - Refining concept mapping word bank to address challenges in coding cognitions
 - Determining how we will assess change in concept maps
- Anticipated publication
 - Refereed journal article
 - Conference presentation at International Symposium on Society and Resource Management in 2020 (Cairns, Australia)

Broader Impacts: Where we are

Curriculum

- Curriculum development nearly complete
- Refining curriculum into single block for summative evaluation

Social science

Formative assessment

- Data collection tools refined
- Writing manuscript

Summative assessment

- Submitting IRB application soon
- Recruiting student teacher participants
- Collect data: Fall 2019/Winter 2020
- Analyze data: Spring/Summer 2020
- Develop manuscript/conference presentation for review

Questions?

- Troy Hall, Professor and Department Head, Forest Ecosystems & Society, troy.hall@oregonstate.edu
- Jay Well, Assistant Director, SMILE Program, jay.well@oregonstate.edu
- Betsy Emery, Graduate Research Assistant, Forest Ecosystems & Society, Elizabeth.emery@oregonstate.edu

Appendix:

Detailed Deliverables
and Milestones

Goal #1: increase HS teachers' content area knowledge, confidence, and materials with emphasis on crop safety and benefits

Proposed Activity	Status (including obstacles & plan revisions)	Output
Formative assessment with teachers	<ul style="list-style-type: none"> Conducted focus groups and surveys with SMILE teachers in April 2018 Used results from those efforts to shape curriculum (found that GMO is not as controversial as expected; teachers have limited confidence to teach this material; students have very brief attention spans and low scientific literacy → significantly down-scaled scope and technical nature of modules). students' lack of digital literacy and rudimentary knowledge of science led us to develop basic modules on these topics apart from GE lessons. 	<ul style="list-style-type: none"> Completed ~40 surveys and 4 focus groups with SMILE teachers during Spring 2018 teacher workshop
SMILE staff teach material to teachers	<ul style="list-style-type: none"> Successful teacher workshops in August 2018, January 2019, and August 2019. 	<ul style="list-style-type: none"> Facilitated 3 separate three-hour workshops with SMILE teachers, totaling 9 hours of professional development for ~40 MS and HS teachers
Annual assessment by teachers of material	<ul style="list-style-type: none"> Need to develop plan to obtain their input about teaching the content. Jay has had informal conversations with teachers that have used the curriculum to gather feedback and efficacy of lessons Teachers have also provided substantial feedback about lessons during the teacher workshops. 	

Goal #2: Increase learners' ability to think critically and introspectively about GT.

Proposed Activity	Status (including obstacles & plan revisions)	Output
Incorporate best practices for curriculum development	<ul style="list-style-type: none"> Used teacher input and existing pedagogical techniques for teaching socio-scientific issues to develop 3 separate units, each with 2-3 individual one hour lessons developed and facilitated an interactive, overnight, educational challenge with 4 separate break out lessons focused on food labeling, how to make a GMO, building a business plan, and merchandising food products for HS students. 	<ul style="list-style-type: none"> 8 individual one-hour lessons about GE, available at http://people.forestry.oregonstate.edu/steve-strauss/genes-affecting-plant-regeneration-and-transformation-poplar 4 one-hour interactive breakout sessions that complement each other
Promote open-minded thinking in curriculum	<ul style="list-style-type: none"> Incorporated activities into the modules the promote discussion, small group sharing, and team work Challenge focused on team work and problem solving as a group 	
Student assessment	<ul style="list-style-type: none"> Had significant delays and challenges with obtaining IRB approval for pilot project in Fall 2018. Abstract

Collecting quantitative data on *in vitro* plant material has long been difficult as it relies on scoring systems that are subjective and time consuming. Oregon State University has partnered with Middleton Spectral Vision (MSV), a Wisconsin-based company, to develop a phenomics pipeline that can efficiently generate high-throughput precision data. This work is part of an NSF Plant Genome Research Program funded study to conduct genome-wide transcriptomic studies (GTAS) to identify genes that determine the site of regeneration and transformation in poplar (*Populus*). The pipeline begins with an RGB and hyperspectral imaging system that is coupled with two modes of data extraction: *FormQuant*TM, a software developed by MSV that can analyze spectral data, and a machine vision system to identify and classify leaves from RGB and ultimately hyperspectral images.

Pipeline overview

Custom imaging system — The MacroPhorTM Array

The MacroPhorTM Array is designed to capture RGB and hyperspectral images across a 24-hour shift configuration. It captures images (can be a 1600-2000 nm) across the spectrum for each plate, which allows for color and precise detection of fluorescence signals including GFP and quantitative analysis of spectral components within a sample.

An 48 sample tray allows for 48 images without producing glare on the tray. The 48 samples are held in a grid of 6 rows and 8 columns, and it is stable in a number of orientations.

A 48-sample tray allows for 48 samples to be detected. GFP, chlorophyll, and other fluorescence signatures in the sample.

Hyperspectral analysis

*FormQuant*TM uses machine learning to convert raw hyperspectral data into a format that is easy to analyze and interpret. It extracts and compares data on a per-plate basis and compares values.

A custom machine vision system was developed so that *FormQuant*TM could recognize leaves in a Petri dish and extract their data automatically.

Key components for an OSU sample include GFP, chlorophyll, and other pigments for each signal.

Machine vision

A 48-sample tray allows for 48 samples to be detected. GFP, chlorophyll, and other fluorescence signatures in the sample.

Results from the first round of data analysis. The middle column shows the user interface for the software, and the right column shows the results from the machine vision system. The left column shows the original images for each plate to be used for the analysis. The middle column shows the results from the machine vision system, which are based on a deep learning (CNN) model.

Current applications

- The Middleton Spectral Vision system extracts unique spectral signatures and quantifies the amount of fluorescent proteins and chlorophyll species in OSU tissue samples.
- Hyperspectral imaging will be used in a pilot study to determine the effectiveness of the developmental genes *SRG1* and *SRG2* to increase resistance of BSWF to stem regeneration in poplar.
- Hyperspectral imaging will allow us to replace the standard GFP reporter with an osain-responsive GFP reporter and cyanine-responsive YFP reporter for early detection of signals.
- FormQuant*TM will help determine the accuracy of the GFP and YFP reporters, and their ability to yield biologically informative data about causes of variation in regeneration and transformation.
- High-throughput RGB imaging with the MacroPhorTM Array will speed and increase the accuracy of phenotypic evaluation.
- Training on the CNN model for image and leaf identification will allow us to test high-throughput leaf analysis in our BSWF study population in research that is currently in progress.

Genome-wide association studies of regeneration in *Populus* with machine vision and hyperspectral phenomics

Introduction

- The recalcitrance of many plant species to *in vitro* regeneration methods prevents researchers from obtaining non-chimeric transformants following genetic transformation.
- Populus trichocarpa* is an ideal model organism for studying regeneration due to amenability to *in vitro* and *in vivo* regeneration protocols.
- Genome-wide association studies (GWAS) can benefit from advances in phenotyping, particularly high throughput phenotyping, hyperspectral imaging and machine vision, to capture a breadth and depth of data that would be practically unobtainable by humans unaided by machines.
- To obtain both RGB and hyperspectral data on a high-throughput scale for *in vitro* plant tissue cultures, we are using the *macroFluo™* Array, a custom instrument from Middleboro Spectral Vision, and the accompanying software suite *KeroQuant™* to deconvolve spectra into individual components, including chlorophylls, fluorescent reporters and spectral shifts.
- Deep learning models using convolutional neural networks are trained to segment images by tissue type (i.e. callus, shoot) after learning from images annotated by a graphical user interface, thus enabling high-throughput and precise analysis of images.

Machine vision

(J) Through a graphical user interface, specific tissues of interest are annotated by the user with assistance by an edge detection algorithm. These annotated images are then used to train convolutional neural networks for image segmentation. Project aims include deployment of this interface as a web server to assist researchers using machine vision.

After learning from user annotations, deep learning models classify sections of images by the type of tissue recognized (J). The accuracy is measurable by comparison to user-annotated images not included in the training set and depends on the type of deep learning architectures used (VGG-16 and PSPNet). Images below are segmented into callus (blue), shoot (green) stem (blue) and background.

Ground truth VGG-16 PSPNet

Hyperspectral analysis

The *macroFluo™* Array (middleborospectralvision.com) is used to capture RGB (M) and hyperspectral images (N-Q) for trays of petri dishes. Deep learning models, while depending on user annotation of RGB images, will also incorporate channels for spectral components provided by hyperspectral analysis. False color applied to GFP and chlorophyll spectral peaks (N) enables qualitative inspection of spectral components of images (N) prior to analysis.

With the software *KeroQuant™*, images are segmented by adjacent (J) and spectral components are identified by multivariate curve resolution and quantified by least squares linear regression (P). For each component, signal intensities are computed per pixel (providing additional image channels to be used for machine vision training and prediction of tissue type) and per experiment (to be used directly in GWAS).

Regeneration

In vitro regeneration

Optimized callus and shoot induction hormone treatments for *in vitro* regeneration from stem and petiole were selected following turbidly leading to determine which cause the highest growth response across genotypes (data not shown). These callus and plant phenotyping has begun and will run through 2023 with 1200 genotypes to be studied.

Stem regeneration

To enhance the natural wounding and regeneration responses, C-Brigit, indole-3-butyric acid (a synthetic cytokinin) was applied to the tips of cut stems. Phenotyping has been completed for 500 of 902 genotypes to be included in the stem regeneration study, and this partial dataset is being used to test and refine GWAS methods.

(A) Stem explant undergoing callus induction and (B) shoot regenerating petiole explant of stem explants undergoing (C) shoot, (D) various stages of callus induction, and (E) later stages of callus growth and shoot regeneration. (F-G) Side view of shoots regenerating from tips of cut stems placed in water; view of stem tip showing several phenotypes recognized by machine vision; (H) green callus; (I) green callus and shoot; (J) red callus and shoot.

Association testing

The GWAS method Sequential Kernel Association Test (SKAT) was used to collapse SNPs into SNPs windows based on physical location and test for associations with traits of interest. To control for non-independence of data, recombination was applied. This test reveals a possible association of shoot area with a flowering of a known shoot regulator in Arabidopsis.

Outlook

- Convolutional neural networks and hyperspectral imaging provide new opportunities for genetic discovery by enabling precise, high-throughput phenotyping of complex traits.
- While currently, most genes in forest species and other non-model plants remain uncharacterized, the advent of high-throughput hyperspectral phenotyping with machine vision may enable rapid identification of these genes via improved power and accuracy for experiments to study gene-function relationships.
- Characterization of the genetic basis of regeneration offers opportunities for converting poor responders to regeneration into efficient responders via overexpression or knockdown/out of developmental regulators. This may enable robust transformation of genotypes and species which genetic engineering methods cannot be efficiently applied to yet.

Summary

- The goal of this project is to develop high-throughput phenotyping systems for studying genetic control of regeneration and transformation in poplar using GWAS.
- A secondary goal is to combine social science research and cross-sector education materials informed by this research, related to understanding GWAS, agriculture, and scientific literacy in the optimization of media world. Key developments to date include: 1) A customized imaging system for high-throughput visible and hyperspectral images of *in vitro* plant materials (total cost for 1M diffuse spectral images); 2) In-depth analysis of *in vitro* regeneration conditions suitable for producing highly heritable regeneration and transformation response in poplar; 3) A machine vision system for rapid phenotyping based on RGB images; 4) Phenotyping of *in vivo* and *in vitro* regeneration response in poplar complex for three GWAS experiments (~1,000 genotypes); 5) GWAS of preliminary data on *in vitro* shoot regeneration from machine vision-generated features (requiring no control genotypes to be identified).

Extensive natural variation in regeneration responses in wild cottonwoods

Our GWAS study relies on naturally high levels of SNP and trait polymorphism, accompanied by low linkage disequilibrium, in wild cottonwood trees, shown as the left and right genotypes (colored) as they regenerate shoots in vivo from cut, dormant stem surfaces over a 5 week experiment (rows).

Shown below are four wild genotypes growing *in vitro* as they regenerate shoots after callus induction. Note the variation in callus size, color, and subsequent shoot size and number.

In Vitro Treatment and Heritability Optimization

To identify conditions that will maximize regeneration, and increase our power to detect causative genes via GWAS, we have explored 1,757 unique combinations of *in vitro* medium-hormone-explant treatments x genotypes over 12 distinct experiments. The figure above summarizes the treatments and explant sources studied or under study.

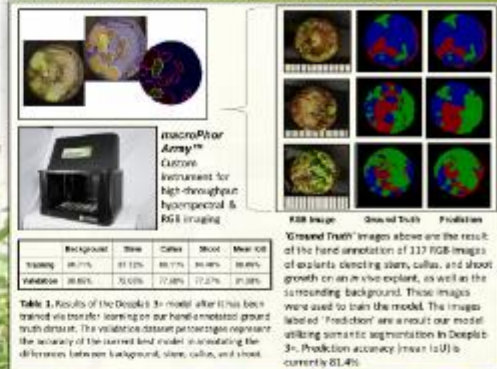

Variation in Phenotypic Responses

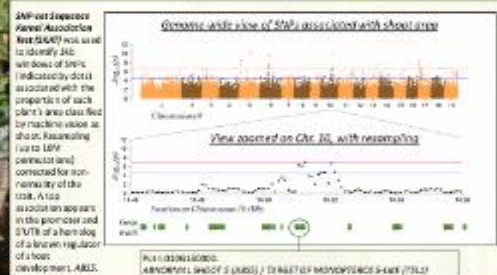

GFP (red) and DsRed (blue) fluorescent markers reduce the presence of a transposon at the insertion site, which can be detected by PCR. The table below shows the results of PCR genotyping for the presence of the transposon in the genome of the explants.

Web- Based Deep Segmentation Tools for Phenotyping

Jialin Yuan¹, Zheng Zhou², Michael Nagle¹, Ekaterina Peremyslova¹, Ali Behnoudfar¹, Nihar A. Doshi³, Ritesh Mewala¹, Cathleen Ma¹, Anna Carina Magnuson¹, Yuan Jiang¹, Steven H. Strauss¹ and Fuxin Li¹

¹. Oregon State University, Corvallis, OR, ². Tencent Inc., ShenZhen, China, ³. University of Southern California, Los Angeles, CA

Motivation

- Quantifying phenotypes of complex biological tissues, such as during in vitro regeneration, is slow and imprecise. Machine vision methods can give a major improvement, but need a user friendly interface (GUI) for annotation of tissues of interest
- Non-web-based IA (Image annotation) tools rely on installation and configuration, often difficult to use
- Existing web-based IA tools, i.e. LabelMe^[1], Labelbox^[2], are expensive and time-consuming to annotate objects at pixel-level accuracy
- Deep learning method is the state-of-art method for segmentation, It is expected to be more efficient and robust to obtain pixel-level annotations

Image Annotator

class/object configuration

- Class Panel:** User can specify the names of the classes
- Hierarchy Panel:** User can specify objects and the classes (parts) they belong to
 - Add multiple classes into an object.
 - Use "add to" to directly add classes.

Toolkit

- Two pens for drawing: *posPen* and *negPen*
- Two modes to annotate target objects:
 - DL-ObjectSelect mode^[3],** draw positive strokes inside one object and negative strokes outside, the UI then automatically generate precise edges along labeling result.
 - Manual mode,** mark objects by directly painting on them.

IO system

- Load multiple Images and view them in the file gallery
- Import and export the configuration of classes and objects
- Save the generated annotation result

History management

- Undo and redo previous drawings to retract wrong operations
- Clear all unwanted *posPen* or *negPen* drawing in one click

Example of Annotating one Image

A GWAS Application

- 103 annotated Images from the Image Annotator
- Trained the PSPNet^[4] for semantic segmentation of background, callus, shoot and stem
- Compute phenotype traits: portion of callus, shoots over stem
- GWAS analysis: normality and association testing (see poster by Michael Nagle for detailed results on GWAS associations)

Conclusion

- We developed a web-based Interactive Image annotation tool
 - There is no need to install any software or configure anything.
 - The user can work from anywhere, anytime with any device or platform.
- Our IA tool is integrated with the DL-ObjectSelect^[3] algorithm, which is easy to use for object segmentation
- We adopted the IA tool in a GWAS study, which proves to be effective in practice, though improvements in annotation databases and prediction efficiency are still under study

Abstract

Collecting quantitative data on *in vitro* plant material has long been difficult as it relies on scoring systems that are subjective and time-consuming. Oregon State University has partnered with Molecular Spectral Vision (MSV) to create a base-1 camera to develop a phenomics pipeline that can efficiently generate high-throughput screening data. The work is part of an NSF Plant Genome Research Program funded study to conduct genome-wide association studies (GWAS) to identify genes that determine the rate of regeneration and transformation in poplar (*Populus*). The pipeline begins with an RGB and hyperspectral imaging system that is coupled with two routes of data extraction: *ImageQuant*™, a software developed by MSV that can analyze spectral data, and a machine vision system to identify and categorize tissues from raw and ultimately hyper-corrected images.

Pipeline overview

Custom imaging system — The MacroPhor™ Array

The MacroPhor™ Array is designed to capture RGB and hyperspectral images across a 24-Petri dish configuration. Hyper-spectral images consist of a 1400-SD (nm) emission spectrum for each pixel, which allows for color and precise detection of fluorescence signals (e.g., GFP), and quantitative analysis of spectral components within a sample.

An SD filter wheel is used to allow for single images without producing glare on the Petri dish lid. Images are available as stacks of Petri dishes, and ring is visible in number labels to the middle-left.

A 488-nm wavelength laser transmits over the Petri dish to detect GFP, chlorophyll, and other fluorescence signatures in the sample.

Hyperspectral analysis

Key to determine whether the raw spectral data is correct is to compare the observed signals with spectral and normally expected data on a given material, as well as compare ratios.

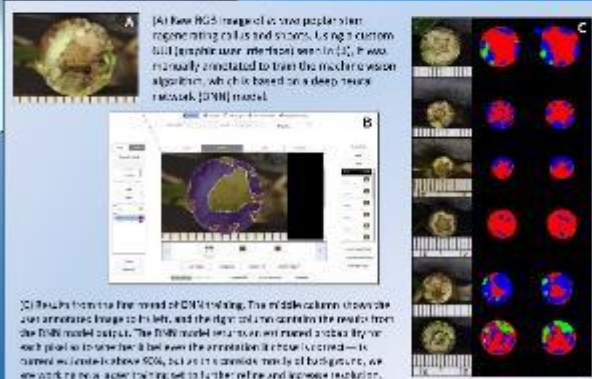

A custom grid now analysis system was developed so that *ImageQuant*™ will recognize tissue elements on a Petri dish and output their data and values.

Five components for an RGB sample include RGB, chlorophyll, a, chlorophyll, and a unique green/red ratio for each signal.

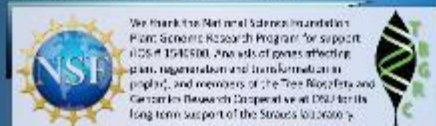

Machine vision

(A) Raw RGB image of a tree poplar stem regeneration cell as well as leaves. Using a custom tool (poplar stem method) seen in (B), it was manually concluded to train the machine vision algorithm, which is based on a deep neural network (DNN) model.

(B) Results from the first round of DNN training. The middle column shows the user annotated image to the left, and the right column contains the results from the DNN model output. The DNN model output was trained to detect GFP by the user prior to whether it had seen the annotation. The model's accuracy is named as shown above 50%, so as it is a random guess of background, we are working on a deeper training set to further refine and increase resolution.

Acknowledgements

Summary

- ▶ The Molecular Spectral Vision system enables consistent, high-throughput, and high-resolution RGB and hyperspectral imaging of tissues in Petri dishes.
- ▶ Its hyperspectral image files are software-enabled unique spectral signatures, including GFP and chlorophyll, to be deconvolved, extracted, and quantified for each specimen.
- ▶ Hyperspectral images at the moment of raw data to quantify information on various genetic variants in common variability using with color and stable fluorescence (GFP/FP).
- ▶ A graphic user interface for an image machine vision has been developed that allows us to specify target classes of tissue types with image tags (e.g., callus, leaves, shoots, roots).
- ▶ Training on the deep neural network model is ongoing and will ultimately allow us to obtain high-throughput non-linear *in vitro* GWAS data on various *in vitro* regeneration and variability that is currently in progress.
- ▶ Phenotyping of *in vitro* regeneration response for GWAS is expected to begin the fall through winter.

Project Overview

Regeneration of differentiated organisms from single cells is a critical need for modern genomics and for the production of genetically engineered organisms. The major bottleneck in genome-wide identification of the genes that control regeneration and transformation (RT) in *Zostera*, which is one of the best studied crop species with respect to these traits. The project will identify genetic elements that control RT, develop novel phenotypic methods for RT analysis, and develop new seed, tissue, and education methods for teaching about genetic engineering to diverse high school students and teachers.

Our project objectives are to: (1) determine a variety of RT methods for use in our research and teaching; (2) develop new phenotypic traits, including an image capture and general color matching system, to precisely determine RT phenotypes (including GWAS, mapping of RT in the genome) with an array of flowering and RT study population parameters with respect to RT rates, developing new studies and new teaching materials, develop the educational and research communities in related fields, and through publications, social media, and conference papers the project's insights and teaching methods immediately.

Why *Zostera* and Ectoderm Induction

Genetic studies require a defined and tractable model organism to determine a shared protocol for inducing cells to shoot growth on defined culture media. *Zostera* has been the model of choice for the study of RT in a range of crop and non-crop plant species because of its high RT rates, its ability to regenerate from single cells, and its ability to regenerate from single cells. We have been the first to demonstrate that *Zostera* can be used as a model for ectoderm induction in a range of crop and non-crop plant species. The project will determine the genetic elements that control RT in *Zostera* and use this information to develop a shared protocol for inducing cells to shoot growth on defined culture media.

Methods Overview of Experiments

The goal of this phase of work is to identify a series of treatments that maximize genetic variance and minimize non-genetic variance in the GWAS analysis. In this work, we identify treatments that give the most variability and that increase RT rates. In a field experiment, we tested 20 field trials types and a number of other variables. In a greenhouse experiment, we tested 20 field trials types and a number of other variables. In a greenhouse experiment, we tested 20 field trials types and a number of other variables. In a greenhouse experiment, we tested 20 field trials types and a number of other variables.

Machine Learning and Graphical User Interface

The goal is to accurately recognize and quantify individual shoot types and sort them into predefined categories (e.g., shoot, stem, and root), as well as to recognize more complex and unfamiliar phenotypic states (e.g., nutrient stressed, nitrogen deficient, necrotic, and modified organ). The approach is to leverage the graphical user interface for image segmentation which allows for a graphical loading panel which an object will be analyzed based on color distribution of the image object. A deep learning algorithm, also trained, will be integrated to further the classification. The importance of the deep learning algorithm and the UI will be to increase prediction power as well as to reduce the processing time, thereby reducing the throughput barrier.

Image Recognition System

The goal is to build a system that can recognize and classify the color and shape of biological objects. The system will be used to analyze the color and shape of biological objects. The system will be used to analyze the color and shape of biological objects. The system will be used to analyze the color and shape of biological objects.

The system will be used to analyze the color and shape of biological objects. The system will be used to analyze the color and shape of biological objects. The system will be used to analyze the color and shape of biological objects.

Genetic Association Studies

As part of plant propagation, we used a GWAS study of in vivo rooting, rooting, and transformation analysis. We used a GWAS study of in vivo rooting, rooting, and transformation analysis. We used a GWAS study of in vivo rooting, rooting, and transformation analysis.

Outreach

We will use the project's findings to develop educational materials for high school students and teachers. We will use the project's findings to develop educational materials for high school students and teachers. We will use the project's findings to develop educational materials for high school students and teachers.

NSF Support

We thank the National Science Foundation (NSF) for its support of this project. We thank the National Science Foundation (NSF) for its support of this project. We thank the National Science Foundation (NSF) for its support of this project.

Overview

- Recalcitrance to *in vitro* regeneration: an obstacle to transformation of many species, particularly woody plants
- Populus trichocarpa* is an ideal model organism for GWAS of regeneration due to variation in transformability, regenerative capacity across genotypes, and diversity across wild populations
- Power and accuracy of GWAS can benefit from new phenotyping methods (high-throughput, hyperspectral, machine vision)
- Through GWAS, we propose that polymorphism in regulation of a known shoot developmental regulator affects shoot regeneration

Plant treatments

In vivo

- Cut stem tips placed in water and treated with cytokinin to promote regeneration
- Imaging of stem tips (below) showing various stages of callus and shoot development

In vitro

- In vitro* treatments used in GWAS were selected for high heritability of regeneration
- Cloning of whole plants with each explant at various stages of normal regeneration

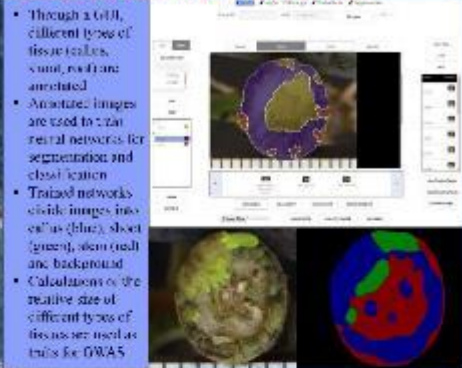

Spectral analysis

- Laser excites fluorophores including chlorophyll and GFP
- Hyperspectral camera collects visible-IR spectra of fluorescence for each pixel; each fluorophore is identified, quantified
- Statistical analysis determines effects of treatments on GFP signal, an indicator of transformation efficiency
- System currently being used to test effects of particular treatments (e.g., auxin, cytokinin, lipole acid, Agrobacterium strains) on transformation rates and for GWAS of *in vitro* regeneration

Machine vision

- Through a GUI, different types of tissue (callus, shoot, root) are annotated
 - Annotated images are used to train neural networks for segmentation and classification
 - Trained networks divide images into "callus" (blue), shoot (green), stem (red) and background
 - Calculations of the relative size of different types of tissues are used as traits for GWAS
- 

Association testing

- The GWAS method Sequence Kernel Association Test (SKAT) was used to collapse SNPs into 5kb windows (shown by data above) and test for their combined effect on shoot regenerated from stem tips
- Shoot area was significantly associated with a homolog of a known shoot regulator that mediates auxin-ethylene crosstalk in Arabidopsis
- Epistatic analysis (EWS) method in PLINK indicates that the effect of this gene depends on a homolog of *LOXRSO47* (*SHCHW47*) ($P < 5 \times 10^{-8}$), but is not significant with 545,450 pairwise tests for epistasis between SNPs of interest. This suggests co-variation of function from Arabidopsis in which *SHCHW47*, *SHCHW2*, *GARS*, and *LHP* must interact with one another to regulate transcription in phloem parenchyma cells of the procambium (Rhee, et al., Dev Cell 2013)

Outlook

- Convolutional neural networks and hyperspectral imaging provide new opportunities for *in vitro* optimization and genetic discovery by enabling precise, high-throughput phenotyping of complex traits
- Characterization of the genetic basis of regeneration offers opportunities for converting poor responders to regenerators into efficient responders via overexpression or knockdown/out of developmental regulators
- Efficient transformation of recalcitrant genotypes may involve a combination of *in vitro* treatments including with auxin/ethylene, as well as genetic treatments such as overexpression of *ARF3* and other developmental regulators

Acknowledgments

We thank the National Science Foundation Plant Genome Research Program for support (DEB-0516900). Analysis of gene expression patterns, genome and metabolite information in poplar, and members of the Bio-Bioinformatics and Bioinformatics Research Center at OSU. An Arizone State support of the Strauss laboratory.
